Abstract

This paper deals with a network of computing agents aiming to solve an online optimization problem in a distributed fashion, i.e., by means of local computation and communication, without any central coordinator. We propose the gradient tracking with adaptive momentum estimation (GTAdam) distributed algorithm, which combines a gradient tracking mechanism with first and second order momentum estimates of the gradient. The algorithm is analyzed in the online setting for strongly convex and smooth cost functions. We prove that the average dynamic regret is bounded and that the convergence rate is linear. The algorithm is tested on a time-varying classification problem, on a (moving) target localization problem and in a stochastic optimization setup from image classification. In these numerical experiments from multi-agent learning, GTAdam outperforms state-of-the-art distributed optimization methods.

1 Introduction

1.1 Online distributed optimization framework

In this paper, we propose a new distributed algorithm for solving online optimization problems over networks of interconnected computing agents. In this framework, agents have only a partial knowledge of the problem to solve,
but can exchange information with neighbors according to a given communication graph and without any central unit. In particular, we consider networks represented by a weighted graph $G = (V, E, W)$, where $V = \{1, \ldots, N\}$ is the set of agents, $E \subseteq V \times V$ is the set of edges (or communication links), and $W \in \mathbb{R}^{N \times N}$ is the (weighted) adjacency matrix of the graph. The matrix $W$ is compliant with the topology described by $E$, i.e., being $w_{ij}$ the $(i,j)$-entry of $W$, then $w_{ij} > 0$ if $(i, j) \in E$ and $w_{ij} = 0$ otherwise. We denote $\mathcal{N}_i = \{j \in V \mid (j, i) \in E\}$ the set of (in-)neighbors of agent $i$.

The aim of the network is to cooperatively solve the online optimization problem

$$\minimize_{x \in \mathbb{R}^n} \sum_{i=1}^{N} f_{i,t}(x), \quad t \geq 0,$$

where each $f_{i,t} : \mathbb{R}^n \to \mathbb{R}$ is a local function revealed only to agent $i$ at time $t$. In the following, we let $f_t(x) \triangleq \sum_{i=1}^{N} f_{i,t}(x)$. This distributed optimization framework captures a variety of estimation and learning problems over networks, including distributed data classification and localization in smart sensor networks.

In this paper, we address the distributed solution of the online optimization problem (1) in terms of dynamic regret (see, e.g., [1, 2, 3]). In particular, let $x_{i,t}$ be the solution estimate of the problem at time $t$ maintained by agent $i$, and let $x_{*,t}$ be a minimizer of $\sum_{i=1}^{N} f_{i,t}(x)$. Then, the agents want to minimize the dynamic regret:

$$R_T \triangleq \sum_{t=1}^{T} f_t(\bar{x}_t) - \sum_{t=1}^{T} f_t(x_{*,t}),$$

for a finite value $T > 1$ with $\bar{x}_t \triangleq \frac{1}{N} \sum_{i=1}^{N} x_{i,t}$.

1.2 Related work

The proposed distributed algorithm combines a gradient tracking mechanism with an adaptive estimation of first and second order momenta. Therefore, we organize the literature review in two main parts reviewing respectively: centralized methods for online and stochastic optimization including algorithms based on adaptive momentum estimation, and distributed algorithms for online optimization and gradient tracking (distributed) schemes (mainly suited for static optimization).

A vast literature on (centralized) online optimization algorithms analyzed through the notion of dynamic regret has been produced in recent
years. Among the others, a generalization of the gradient method is proposed in [1] to address online convex programs, and regret bounds are studied in [3]. In [4], a tighter regret bound for non-degenerate functions is provided. In [5, 6] prediction-correction schemes are proposed to solve convex online optimization problems. The tracking of time-varying parameters with unknown dynamics is addressed in [7]. Dynamic resource allocation problems over networks are studied in [8], while a personalized optimization setup is introduced in [9]. It is worth noting that online optimization is strictly related to stochastic optimization. In fact, stochastic problems may be seen as online ones in which the sequence of objective functions is known to possess a particular probabilistic structure. Mostly due to their relevance in machine learning problems, many algorithms dealing with stochastic problems flourished in recent years. Starting from the classical stochastic gradient descent [10], a number of methods based on momentum estimation and adaptive step-size choices have been proposed [11, 12, 13, 14]. In particular, Adam algorithm, originally proposed in [14], is a method based on adaptive estimates of first and second order gradient momenta that has been successfully employed in many problems. Adam combines the advantages of the popular methods AdaGrad and RMSProp, respectively proposed in [11] and [13]. Additional insights about Adam are given in [15, 16, 17] and [18], where some frameworks in which the algorithm is not able to reach the optimal solution are also shown. This limitation is deeply studied in [19], where a sufficient condition for convergence is formally established, and is further addressed in [20] where an effective extension of Adam, namely AdaShift, is proposed.

Optimization problems characterized by time-varying cost functions have been also widely investigated in the distributed optimization literature. In [21] an online optimization algorithm based on a distributed subgradient scheme is proposed. In [22] an adaptive diffusion algorithm is proposed to address changes regarding both the cost function and the constraints characterizing the problem. A class of coordination algorithms that generalize distributed online subgradient descent and saddle-point dynamics is proposed in [23] for network scenarios modeled by jointly-connected graphs. An algorithm consisting of a subgradient flow combined with a push-sum consensus is studied in [24] for time-varying directed graphs. Cost uncertainties and switching communication topologies are addressed in [25] by using a distributed algorithm based on dual subgradient averaging. A distributed version of the mirror descent algorithm is proposed in [26] to address online optimization problems. In [27] an online algorithm based on the alternating direction method of multipliers is proposed, and in [28] time-varying inequal-
ity constraints are also considered. Regarding distributed algorithms for stochastic optimization, in [29] authors investigate the convergence properties of a distributed algorithm dealing with subgradients affected by stochastic errors. In [30] convex problems in multi-agent learning are addressed by enhancing a distributed stochastic subgradient with graph-dependent implicit regularization strategies. In [31] a block-wise method is proposed to deal with high-dimensional stochastic problems, while in [32] a distributed gradient tracking method is analyzed in a stochastic setup.

The gradient tracking scheme, which we extend in the present paper, has been proposed in several variants in recent years and studied under different problem assumptions [33, 34, 35, 36, 37, 38, 39, 40, 41]. This algorithm leverages a “tracking action” based on the dynamic average consensus (see [42, 43]) in order to let the agents obtain a local estimate of the gradient of the whole cost function. In [44] gradient tracking has been combined with successive convex approximation techniques to solve (nonconvex) dictionary learning problems in a distributed way. Recently, in [45] the gradient tracking algorithm has been applied to online optimization problems. Finally, in [46] a dynamic gradient tracking update is combined with a recursive least squares scheme to solve in a distributed way online optimization problems in which the local functions are partially unknown.

1.3 Contribution

The main contribution of this paper is the design of a new distributed algorithm to solve online optimization problems for multi-agent learning over networks. This novel scheme builds on the recently proposed gradient tracking distributed algorithm. Specifically, in the gradient tracking the agents update their local solution estimates using a consensus averaging scheme perturbed with a local variable representing a descent direction. This variable is concurrently updated using a dynamic consensus scheme aiming at reconstructing the total cost function gradient in a distributed way. Inspired by the centralized Adam algorithm, we accelerate the basic gradient tracking scheme by enhancing the descent direction resorting to first and second order momenta of the cost function gradient. The use of momenta turned out to be very effective in the centralized Adam to solve online optimization problems with a fast rate. Therefore, we design our novel gradient tracking with adaptive momentum estimation (GTAdam) distributed algorithm to solve online optimization problems over networks. The algorithm relies on local estimators for the two momenta, in which the total gradient is replaced by a (local) gradient tracker. Although the intuition behind the construction
of GTAdam is clear and consists of mimicking the centralized Adam in a distributed setting by using a gradient tracking scheme, its analysis presents several additional challenges with respect to both the gradient tracking and Adam. Indeed, being the descent direction a nonlinear combination of the local states updated through a consensus averaging, the proof approach of the gradient tracking needs to be carefully reworked. We show that the incurred dynamic regret for strongly convex online optimization problems is linearly bounded as the iterations proceed. Finally, we perform extensive numerical simulations on three application scenarios from distributed machine learning: a classification problem via logistic regression, a source localization problem in smart sensor networks and an image classification task. In all cases, we show that GTAdam outperforms the current state-of-the-art distributed online optimization methods in terms of convergence rate.

1.4 Organization and Notation

The rest of the paper is organized as follows. In Section 2 we briefly recall the two algorithms that inspired the novel distributed algorithm proposed in this paper. In Section 3 GTAdam is presented with its convergence properties which are then proved in Section 4. Finally, Section 5 shows numerical examples highlighting the advantages of the proposed algorithm.

Notation. We use $\text{col}(v_1, v_2)$ to denote the vertical concatenation of the column vectors $v_1$ and $v_2$. We use $\text{diag}(v)$ to denote the diagonal matrix with diagonal elements given by the components of $v$. The symbol $\odot$ denotes the Hadamard product, while the Kronecker product is denoted by $\otimes$. The identity matrix in $\mathbb{R}^{m \times m}$ is $I_m$, while $0_m$ is the zero matrix in $\mathbb{R}^{m \times m}$. The column vector of $N$ ones is denoted by $1_N$ and we define $1 \triangleq 1_N \otimes I_d$. Dimensions are omitted whenever they are clear from the context.

2 Inspiring algorithms

In this section we briefly recall two existing algorithms that represent the building blocks for GTAdam, namely the Adam centralized algorithm and the gradient tracking distributed algorithm.
2.1 Adam centralized algorithm

Adam \[14\] is an optimization algorithm that solves problems in the form \((1)\) in a centralized computation framework. It is an iterative gradient-like procedure in which, at each iteration \(t\), a solution estimate \(x_t\) is updated by means of a descent direction which is enhanced by a proper use of the gradient history, i.e., through estimates of their first and second order momenta. Specifically, the (time-varying) gradient \(\nabla f_t(x_t)\) of the function drives two exponential moving average estimators. The two estimates, denoted by \(m_t\) and \(v_t\), represent, respectively, mean and variance (1st and 2nd momentum) of the gradient sequence and are nonlinearly combined to build the descent direction. A pseudo-code of Adam algorithm is reported in Table 1 in which \(\alpha > 0\) is the usual fixed step-size used for scaling the descent direction, the constant \(0 < \epsilon \ll 1\) is introduced to guarantee numerical robustness of the scheme, while the hyper-parameters \(\beta_1, \beta_2 \in (0, 1)\) control the exponential-decay rate of the moving average dynamics.

Algorithm 1 Adam

choose: \(\alpha > 0, \beta_1 \in (0, 1), \beta_2 \in (0, 1), 0 < \epsilon \ll 1\)
initialization: \(x_0\) arbitrary, \(m_0 = v_0 = 0, g_0 = \nabla f_0(x_0)\)

for \(t = 1, 2 \ldots\) do
\[
\begin{align*}
  m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_{t-1} \\
  v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_{t-1} \odot g_{t-1} \\
  x_t &= x_{t-1} - \alpha \frac{1 - \beta_2}{1 - \beta_1^2} \frac{m_t}{\sqrt{v_t + \epsilon}} \\
  g_t &= \nabla f_t(x_t)
\end{align*}
\]
end for

As customary in the literature, we point out that in the algorithm above the ratio \(\frac{m_t}{\sqrt{v_t + \epsilon}}\) is meant element-wise. Typical choices for the algorithmic parameters are \(\beta_1 = 0.9, \beta_2 = 0.999,\) and \(\epsilon = 10^{-8}\).

2.2 Gradient tracking distributed algorithm

The gradient tracking is a distributed algorithm mainly tailored to static instances of problem \((1)\). Agents in a network maintain and update two local states \(x_{i,t}\) and \(s_{i,t}\) by iteratively combining a perturbed average consensus and a dynamic tracking mechanism. Consensus is used to enforce agreement
among the local agents’ estimates $x_{i,t}$. The agreement is also locally perturbed in order to steer the local estimates toward a (static) optimal solution of the problem. The perturbation is obtained by using a tracking scheme that allows agents to locally reconstruct a progressively accurate estimate of the whole gradient of the (static) cost function in a distributed way. A pseudo-code of the gradient tracking distributed algorithm is reported in Table 2, where we recall that $\mathcal{N}_i$ denotes the set of (in-)neighbors of agent $i$, while $\alpha > 0$ is the usual fixed step-size used to scale the local descent direction $s_{i,t}$. Notice that Table 2 shows the algorithm from the perspective of agent $i$ only.

3 Gradient tracking with adaptive momentum estimation

In this section we present the main contribution of this paper, i.e., the Gradient tracking with adaptive momentum estimation (GTAdam) distributed algorithm. GTAdam is designed to address in a distributed fashion problem (1), taking inspiration both from Adam and from the gradient tracking distributed algorithm.

Along the evolution of the algorithm, each agent $i$ maintains four local quantities:

(i) a local estimate $x_{i,t}$ of the current optimal solution $x_*$;

(ii) an auxiliary variable $s_{i,t}$ whose role is to track the gradient of the whole cost function;
(iii) an estimate $m_{i,t}$ of the 1st momentum of $s_{i,t}$;

(iv) an estimate $v_{i,t}$ of the 2nd momentum of $s_{i,t}$.

The momentum estimates of $s_{i,t}$ are initialized as $m_{i,t} = v_{i,t} = 0$, while the tracker of the gradient is initialized as $s_{i,0} = \nabla f_{i,0}(x_{i,0})$.

The algorithm works as follows. At each time instant $t$, each agent $i$ performs the following operations

(i) it updates the moving averages $m_{i,t}$ and $v_{i,t}$;

(ii) it computes a weighted average of the solution estimates of its neighbors and, starting from this point, it uses the update direction $\frac{m_{i,t}}{\sqrt{v_{i,t} + \epsilon}}$ to compute the new solution estimate $x_{i,t}$;

(iii) it updates the local gradient tracker $s_{i,t}$ via a dynamic consensus mechanism.

Algorithm 3 GTAdam (for agent $i$)

```
choose: $\alpha > 0$, $\beta_1 \in (0, 1)$, $\beta_2 \in (0, 1)$, $0 < \epsilon \ll 1$
initialization: $x_{i,0}$ arbitrary, $s_{i,0} = g_{i,0} = \nabla f_{i,0}(x_{i,0})$, $m_{i,0} = v_{i,0} = 0$

for $t = 1, \ldots, T$
do
  $m_{i,t} = \beta_1 m_{i,t-1} + (1 - \beta_1) s_{i,t-1}$
  $v_{i,t} = \min\{\beta_2 v_{i,t-1} + (1 - \beta_2) s_{i,t-1} \otimes s_{i,t-1}, G\}$
  $x_{i,t} = \sum_{j \in \mathcal{N}_i} w_{ij} x_{j,t-1} - \alpha \frac{m_{i,t}}{\sqrt{v_{i,t} + \epsilon}}$
  $g_{i,t} = \nabla f_{i,t}(x_{i,t})$
  $s_{i,t} = \sum_{j \in \mathcal{N}_i} w_{ij} s_{j,t-1} + g_{i,t} - g_{i,t-1}$
end for
```

We now state the convergence properties of the proposed GTAdam algorithm in terms of dynamic regret. To this end, we start by posing some regularity requirements on problem [1]. We first make two assumptions regarding each $f_{i,t}$. 

A pseudo-code of GTAdam is reported in Table [3]. Notice that, a saturation term $G \gg 0$ is introduced in the updated of $v_{i,t}$, where the min operator is to be intended element-wise.
**Assumption 3.1** (Lipschitz continuous gradients). The functions $f_{i,t}$ have $L$-Lipschitz continuous gradients for all $i$ and $t$.

**Assumption 3.2** (Strong convexity). The functions $f_{i,t}$ are $q$-strongly convex for all $i$ and $t$.

The following assumption concerns the time-varying structure of the optimization problem.

**Assumption 3.3** (Bounded variations). There exist two positive constants $\eta$ and $\zeta$ such that, for all $t$, it holds

$$\eta_t \triangleq \max_i \max_{x \in \mathbb{R}^n} \| \nabla f_{i,t}(x) - \nabla f_{i,t-1}(x) \| \leq \eta$$

and

$$\zeta_t \triangleq \| x_{*,t} - x_{*,t-1} \| \leq \zeta.$$

These requirements are common in the literature about online optimization. We point out that, in light of Assumption 3.2, the minimizer $x_{*,t}$ is unique for all $t$. Moreover, notice that Assumption 3.3 specifies that $f_t$ must be sufficiently regular also with respect to $t$.

Finally, the following assumption characterizes the communication network structure.

**Assumption 3.4** (Network structure). The weighted communication graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, W)$ is strongly connected and the matrix $W$ is doubly stochastic, i.e., $\sum_{i=1}^N w_{ij} = 1$, and $\sum_{j=1}^N w_{ij} = 1$, for all $i, j \in \mathcal{V}$, with $w_{ij}$ being the $(i,j)$-entry of $W$.

In order to analyze GTAdam, we start by rewriting it in an aggregate form. Given the set of variables $\{x_{i,t}\}_{i=1}^N$, we define $x_t \triangleq \text{col}(x_{1,t}, \ldots, x_{N,t})$ and its average as $\bar{x}_t \triangleq \frac{1}{N} \sum_{i=1}^N x_{i,t}$. Similar definitions apply to the quantities $m_t, v_t, d_t, g_t, s_t$ and the averages $\bar{m}_t, \bar{v}_t, \bar{d}_t, \bar{s}_t$. With these definitions at hand, the GTAdam algorithm can be rephrased in a global perspective as

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) s_{t-1}$$

(5a)

$$v_t = \min \{ \beta_2 v_{t-1} + (1 - \beta_2) s_{t-1} \odot s_{t-1}, 1G \}$$

(5b)

$$d_t = (V_t + \epsilon I)^{-1/2} m_t$$

(5c)

$$x_t = W x_{t-1} - \alpha d_t$$

(5d)

$$s_t = W s_{t-1} + g_t - g_{t-1},$$

(5e)

in which we set $V_t \triangleq \text{diag}(v_t)$ and $\bar{V}_t \triangleq \text{diag}(\bar{v}_t)$. 

9
Moreover, the averages evolve according to

\[
\begin{align*}
\bar{m}_t &= \beta_1 \bar{m}_{t-1} + (1 - \beta_1) \bar{s}_{t-1} \\
\bar{v}_t &= \min\{\beta_2 \bar{v}_{t-1} + (1 - \beta_2) \bar{s}_{t-1} \odot \bar{s}_{t-1}, G\} \\
\bar{d}_t &= \frac{1}{N} \mathbf{1}^\top \mathbf{d}_t \\
\bar{x}_t &= \bar{x}_{t-1} - \alpha \bar{d}_t \\
\bar{s}_t &= \bar{s}_{t-1} + \frac{1}{N} \sum_{i=1}^{N} (g_{i,t} - g_{i,t-1}).
\end{align*}
\] (6a, 6b, 6c, 6d, 6e)

Our analysis is based on studying the aggregate dynamical evolution of the following norms: average first momentum \(\|\bar{m}_t\|\), average tracking momentum difference \(\|\bar{s}_t - \bar{m}_t\|\), first momentum error \(\|\mathbf{m}_t - 1\bar{m}_t\|\), gradient tracking error \(\|\mathbf{s}_t - 1\bar{s}_t\|\), consensus error \(\|\bar{x}_t - 1\bar{x}_t\|\) and solution error \(\|\bar{x}_t - x_{*,t}\|\).

Let us define \(y_t\) as the vector stacking all the above quantities at iterations \(t\), i.e.,

\[
y_t \triangleq \begin{bmatrix}
\|\bar{m}_t\| \\
\|\bar{s}_t - \bar{m}_t\| \\
\|\mathbf{m}_t - 1\bar{m}_t\| \\
\|\mathbf{s}_t - 1\bar{s}_t\| \\
\|\bar{x}_t - 1\bar{x}_t\| \\
\|\bar{x}_t - x_{*,t}\|
\end{bmatrix}.
\] (7)

Then, the main result of this paper is stated as follows.

**Theorem 3.5.** Let Assumptions 3.1, 3.2, 3.3 and 3.4 hold. For sufficiently small values of the step-size \(\alpha\), there exists a positive constant \(\rho(\alpha) < 1\), for which

\[
f_t(\bar{x}_t) - f_t(x_{*,t}) \leq \frac{L}{2} \left( \rho(\alpha)^{2t} \|y_0\|^2 + 2\rho(\alpha)^t \|y_0\| \sqrt{Q} \frac{Q}{1 - \rho(\alpha)} + \frac{Q}{1 - \rho(\alpha)^2} \right),
\] (8)

where \(Q \triangleq \frac{L^2\eta^2}{N} + N\eta^2 + \zeta^2\).

The proof of Theorem 3.5 requires several intermediate results and is carried out in Section 4. Notice that Theorem 3.5 implies that \(f_t(\bar{x}_t) - f_t(x_{*,t})\) decays to \(\frac{L}{2} \frac{Q}{(1 - \rho(\alpha))^2}\) with linear rate \(O(\rho(\alpha)^t)\). Therefore, the following corollary holds true.
Corollary 3.6 (Bounded average dynamic regret). Under the same assumptions of Theorem 3.5, it holds that

$$\limsup_{T \to \infty} \frac{R_T}{T} \leq \frac{L}{2} \frac{Q}{(1 - \rho(\alpha))^2},$$

with $R_T$ defined as in (2) while $\rho(\alpha)$ and $Q$ are the same as in Theorem 3.5.

4 Analysis

This section is devoted to provide the proof for Theorem 3.5.

4.1 Preparatory Lemmas

We now give a sequence of intermediate results, providing proper bounds on the components of $y_t$ (defined in (7)), that are then used as building blocks for proving Theorem 3.5. All the next results refer to the updates defined in (5) and (6).

Lemma 4.1 (First momentum error). For all $t \geq 1$, it holds

$$\|m_t - \bar{m}_t\| \leq \beta_1 \|m_{t-1} - \bar{m}_{t-1}\| + (1 - \beta_1) \|s_{t-1} - \bar{s}_{t-1}\|. \quad (10)$$

Proof. By using (5a) and (6a), one has

$$\|m_t - \bar{m}_t\| = \|\beta_1 m_{t-1} + (1 - \beta_1) s_{t-1} - 1(\beta_1 \bar{m}_{t-1} + (1 - \beta_1) \bar{s}_{t-1})\| \leq \beta_1 \|m_{t-1} - \bar{m}_{t-1}\| + (1 - \beta_1) \|s_{t-1} - \bar{s}_{t-1}\|,$$

where in (a) we use the triangle inequality.

Lemma 4.2 (Input signal error). For all $t \geq 1$, it holds

$$\|d_t - \bar{d}_t\| \leq \frac{\beta_1}{\sqrt{\epsilon}} \|m_{t-1} - \bar{m}_{t-1}\| + \frac{1 - \beta_1}{\sqrt{\epsilon}} \|s_{t-1} - \bar{s}_{t-1}\|. \quad (11)$$

Proof. By using (5c) and (6c), one has

$$\|d_t - \bar{d}_t\| = \| (V_t + \epsilon I)^{-1/2} m_t - \frac{1}{\sqrt{\epsilon}} 11^T (V_t + \epsilon I)^{-1/2} m_t \|. \quad (12)$$
Consider the right-hand term of (11)

\[
\| (V_t + \epsilon I)^{-1/2} m_t - \frac{1}{\sqrt{N}} 1^T (V_t + \epsilon I)^{-1/2} m_t \| = \left\| \left( I - \frac{1}{N} 1^T \right) (V_t + \epsilon I)^{-1/2} m_t \right\|
\]

\[
\leq \left\| \left( I - \frac{1}{N} 1^T \right) (\epsilon I)^{-1/2} m_t \right\|
\]

\[
= \frac{1}{\sqrt{\epsilon}} \left\| \left( I - \frac{1}{N} 1^T \right) m_t \right\|
\]

\[
\leq \frac{1}{\sqrt{\epsilon}} \left\| \left( I - \frac{1}{N} 1^T \right) (m_t - \bar{m}_t) \right\|,
\]

where in (a) we use the fact that \((V_t + \epsilon I)^{-1/2} \leq \frac{1}{\sqrt{\epsilon}}\) for all \(t \geq 0\), and in (b) we exploit the property \(1 \in \ker (I - \frac{1}{N} 1^T)\). Thus, since \(\| I - \frac{1}{N} 1^T \| \leq 1\) we can finally write

\[
\| d_t - 1 d_t \| \leq \frac{1}{\sqrt{\epsilon}} \| (m_t - 1 \bar{m}_t) \|,
\]

The proof is completed by using Lemma 4.1.

\[ \square \]

**Lemma 4.3** (Consensus error). Let Assumptions 3.1, and 3.4 hold. Then, for all \(t \geq 1\), it holds

\[
\| x_t - 1 \bar{x}_t \| \leq \sigma_W \| x_{t-1} - 1 \bar{x}_{t-1} \| + \frac{\alpha \beta_1}{\sqrt{\epsilon}} \| m_{t-1} - 1 \bar{m}_{t-1} \|
\]

\[
+ \frac{\alpha(1 - \beta_1)}{\sqrt{\epsilon}} \| s_{t-1} - 1 \bar{s}_{t-1} \|,
\]

where \(\sigma_W \in (0, 1)\) is the spectral radius of \(W - \frac{1}{N} 1^T\).

**Proof.** By combining (5d) and (6d), we have

\[
\| x_t - 1 \bar{x}_t \| = \| W x_{t-1} - \alpha d_t - 1 \bar{x}_{t-1} + \alpha 1 d_t \|.
\]

By using the triangle inequality, we get

\[
\| x_t - 1 \bar{x}_t \| \leq \| W x_{t-1} - 1 \bar{x}_{t-1} \| + \alpha \| d_t - 1 \bar{d}_t \|
\]

\[
\leq \sigma_W \| x_{t-1} - 1 \bar{x}_{t-1} \| + \alpha \| d_t - 1 \bar{d}_t \|,
\]

where (a) follows from standard properties of stochastic matrices. Then, it is sufficient to apply Lemma 4.2 to conclude the proof.

\[ \square \]
Lemma 4.4 (Average first momentum magnitude). Let Assumption 3.1 hold. Then, for all \( t \geq 1 \), it holds
\[
\|\bar{m}_t\| \leq \beta_1 \|\bar{m}_{t-1}\| + \frac{(1 - \beta_1)L}{\sqrt{N}} \|\mathbf{x}_{t-1} - \mathbf{1}\bar{x}_{t-1}\| + (1 - \beta_1)L \|\bar{x}_{t-1} - x_{*,t-1}\|. \tag{13}
\]

Proof. By using (6a), one has
\[
\|\bar{m}_t\| = \|\beta_1\bar{m}_{t-1} + (1 - \beta_1)\bar{s}_{t-1}\|
\leq \beta_1 \|\bar{m}_{t-1}\| + (1 - \beta_1)\|\bar{s}_{t-1}\|,
\]
in which we use the triangle inequality. Regarding the term \( \|\bar{s}_{t-1}\| \), we use the relation \( \bar{s}_{t-1} = \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \), and we add \( \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{*,t-1}) = 0 \), thus obtaining
\[
\|\bar{s}_{t-1}\| = \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{*,t-1}) \right\|
\leq \frac{L}{N} \sum_{i=1}^{N} \|x_{i,t-1} - x_{*,t-1}\|
\leq \frac{L}{\sqrt{N}} \|x_{t-1} - \mathbf{1}x_{*,t-1}\|
\leq \frac{L}{\sqrt{N}} \|x_{t-1} - \mathbf{1}\bar{x}_{t-1}\| + L \|\bar{x}_{t-1} - x_{*,t-1}\|,
\]
where in (a) we exploit Assumption 3.1, in (b) we use the basic algebraic property \( \sum_{i=1}^{N} \|\theta_i\| \leq \sqrt{N} \|\theta\| \) for a generic vector \( \theta \triangleq \text{col}(\theta_1, \ldots, \theta_N) \), and in (c) we add and subtract the term \( \mathbf{1}\bar{x}_{t-1} \) and apply the triangle inequality.

Lemma 4.5 (Tracking error). Let Assumptions 3.1, 3.2, 3.3 and 3.4 hold. Then, for all \( t \geq 1 \), it holds
\[
\|s_t - \mathbf{1}\bar{s}_t\| \leq \left( \sigma_W + \frac{\alpha L (1 - \beta_1)}{\sqrt{\epsilon}} \right) \|s_{t-1} - \mathbf{1}\bar{s}_{t-1}\|
+ \left( L \|W - I\| + \frac{\alpha (1 - \beta_1)L^2}{\sqrt{\epsilon}} \right) \|x_{t-1} - \mathbf{1}\bar{x}_{t-1}\|
+ \frac{\alpha (1 - \beta_1)L^2 \sqrt{N}}{\sqrt{\epsilon}} \|\bar{x}_{t-1} - x_{*,t-1}\| + \frac{\alpha \beta_1 L \sqrt{N}}{\sqrt{\epsilon}} \|\bar{m}_{t-1}\| + \sqrt{N} \eta_t
+ \frac{\alpha L \beta_1}{\sqrt{\epsilon}} \|m_{t-1} - \mathbf{1}\bar{m}_{t-1}\|, \tag{14}
\]
where \( \sigma_W \in (0, 1) \) is the spectral radius of \( W - \frac{1}{N} \mathbf{1}\mathbf{1}^\top \).
Proof. By combining (5e) and (6e) one has

\[ \| s_t - 1 \bar{s}_t \| = \left\| W s_{t-1} + g_t - g_{t-1} - 1 \left( \bar{s}_{t-1} + \frac{1}{N} \sum_{i=1}^N (g_{i,t} - g_{i,t-1}) \right) \right\| \]

\[ \begin{aligned}
\leq & \quad \left\| W s_{t-1} - 1\bar{s}_{t-1} \right\| + \left\| g_t - g_{t-1} - 1 \left( \frac{1}{N} \sum_{i=1}^N (g_{i,t} - g_{i,t-1}) \right) \right\| \\
= & \quad \left\| W s_{t-1} - 1\bar{s}_{t-1} \right\| + \left\| \left( I - \frac{1}{N} 11^\top \right) (g_t - g_{t-1}) \right\| \\
= & \quad \left\| \left( W - \frac{1}{N} 11^\top \right) s_{t-1} \right\| + \left\| \left( I - \frac{1}{N} 11^\top \right) (g_t - g_{t-1}) \right\| \\
\overset{(b)}{=} & \quad \left\| \left( W - \frac{1}{N} 11^\top \right) (s_{t-1} - 1\bar{s}_{t-1}) \right\| + \left\| \left( I - \frac{1}{N} 11^\top \right) (g_t - g_{t-1}) \right\|,
\end{aligned} \]

where (a) uses the triangle inequality and (b) uses the fact that \( 1 \in \ker (W - \frac{1}{N} 11^\top) \).

So,

\[ \| s_t - 1\bar{s}_t \| \leq \sigma_W \| s_{t-1} - 1\bar{s}_{t-1} \| + \left\| I - \frac{1}{N} 11^\top \right\| \left\| g_t - g_{t-1} \right\| \]

\[ \overset{(a)}{\leq} \sigma_W \| s_{t-1} - 1\bar{s}_{t-1} \| + \| g_t - g_{t-1} \|, \tag{15} \]

where in (a) we use \( \left\| I - \frac{1}{N} 11^\top \right\| \leq 1 \), and \( \sigma_W \in (0, 1) \) is the spectral radius of the matrix \( W - \frac{1}{N} 11^\top \). Let

\[ \tilde{g}_t \triangleq \text{col}(\nabla f_{1,t}(x_{1,t-1}), \ldots, \nabla f_{N,t}(x_{N,t-1})). \]

Let us now manipulate the term \( \| g_t - g_{t-1} \| \),

\[ \| g_t - g_{t-1} \| \leq \| g_t - \tilde{g}_t \| + \| \tilde{g}_t - g_{t-1} \| \]

\[ \overset{(a)}{\leq} L \| x_t - x_{t-1} \| + \| \tilde{g}_t - g_{t-1} \| \]

\[ \overset{(b)}{\leq} L \| x_t - x_{t-1} \| + \sqrt{N} \eta_t \]

\[ \overset{(c)}{=} L \| W x_{t-1} - \alpha d_t - x_{t-1} \| + \sqrt{N} \eta_t, \tag{16} \]

where we use in (a) Assumption 3.1, in (b) Assumption 3.3 and in (c) the update (5d) of \( x_t \). Let us now manipulate the first term on the right-hand
side of (16):

\[ \| W x_{t-1} - \alpha d_t - x_{t-1} \| = \| (W - I) x_{t-1} - \alpha d_t \| \]
\[ \overset{(a)}{=} \| (W - I) (x_{t-1} - \bar{x}_{t-1}) - \alpha d_t \| \]
\[ \leq \| (W - I) (x_{t-1} - \bar{x}_{t-1}) \| + \alpha \| d_t \| \]
\[ \leq \| W - I \| \| x_{t-1} - \bar{x}_{t-1} \| + \alpha \| d_t \| \]
\[ \overset{(b)}{=} \| W - I \| \| x_{t-1} - \bar{x}_{t-1} \| + \alpha \| d_t - \bar{d}_t \| + \alpha \| \tilde{d}_t \|, \]

(17)

where (a) uses the fact that \( 1 \in \ker (W - I) \) and in (b) we add and subtract the term \( \tilde{d}_t \). Regarding the last term we can use (5c) and (6c) to write

\[ \| \tilde{d}_t \| = \left\| \frac{1}{N} 11^\top d_t \right\| \]
\[ = \left\| \frac{1}{N} 11^\top (V_t + \epsilon I)^{-1/2} m_t \right\| \]
\[ \overset{(a)}{\leq} \frac{1}{\sqrt{\epsilon}} \left\| \frac{1}{N} 11^\top m_t \right\| \]
\[ = \frac{1}{\sqrt{\epsilon}} \| \bar{m}_t \| \]
\[ \overset{(b)}{= } \frac{\sqrt{N}}{\sqrt{\epsilon}} \| \bar{m}_t \|, \]

(18)

where (a) uses the fact that \( \| (V_t + \epsilon I)^{-1/2} \| \leq \frac{1}{\sqrt{\epsilon}} \) and (b) uses the basic algebraic property \( \sum_{i=1}^N \| \theta_i \| \leq \sqrt{N} \| \theta \| \) for any vector \( \theta \triangleq \text{col}(\theta_1, \ldots, \theta_N) \).

The proof is completed by using Lemma 4.4 within (18) and by combining it with (15), (16) and (17).

**Lemma 4.6** (Tracking momentum difference magnitude). Let Assumptions 3.1, 3.2, 3.3 and 3.4 hold. Then, for all \( t \geq 1 \), it holds

\[ \| \tilde{s}_t - \bar{m}_t \| \leq \beta_1 \| \tilde{s}_{t-1} - \bar{m}_{t-1} \| \]
\[ + \left( \sigma_W \frac{L}{\sqrt{N}} + \frac{L}{\sqrt{N}} + \frac{\alpha(1 - \beta_1)L^2}{\sqrt{\epsilon N}} \right) \| x_{t-1} - \bar{x}_{t-1} \| \]
\[ + \frac{\alpha \beta_1 L}{\sqrt{\epsilon \sqrt{N}}} \| m_{t-1} - \bar{m}_{t-1} \| + \frac{\alpha \beta_1 L}{\sqrt{\epsilon \sqrt{N}}} \| s_{t-1} - \bar{s}_{t-1} \| + \frac{L}{\sqrt{N}} \eta_{t-1} \]
\[ + \frac{\alpha \beta_1 L}{\sqrt{\epsilon \sqrt{N}}} \| \bar{m}_{t-1} \| + \frac{\alpha(1 - \beta_1)L^2}{\sqrt{\epsilon \sqrt{N}}} \| \bar{x}_{t-1} - x_{*,t-1} \|, \]

(19)

where \( \sigma_W \in (0, 1) \) is the spectral radius of \( W - \frac{1}{N} 11^\top \).
Proof. By using the updates of $\bar{s}_t$ and $\bar{m}_t$ in (6e) and (6a), we get

$$\|\bar{s}_t - \bar{m}_t\|$$
$$= \left\| \bar{s}_{t-1} + \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) - \beta_1 \bar{m}_{t-1} - (1 - \beta_1)\bar{s}_{t-1} \right\|$$
$$(a) \leq \beta_1 \|\bar{s}_{t-1} - \bar{m}_{t-1}\| + \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \right\|,$$

where $(a)$ uses the triangle inequality. Now we add and subtract within the second norm the terms $\frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(\bar{x}_t)$ and $\frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t-1})$ and use the triangle inequality to obtain

$$\|\bar{s}_t - \bar{m}_t\| \leq \beta_1 \|\bar{s}_{t-1} - \bar{m}_{t-1}\| + \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(\bar{x}_t) \right\|$$
$$+ \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t-1}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \right\|$$
$$+ \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(\bar{x}_t) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t}(x_{i,t-1}) \right\|$$
$$(a) \leq \beta_1 \|\bar{s}_{t-1} - \bar{m}_{t-1}\| + \frac{L}{\sqrt{N}} \|x_t - 1\bar{x}_t\| + \frac{L}{\sqrt{N}} \eta_{t-1} + \frac{L}{\sqrt{N}} \|x_{t-1} - 1\bar{x}_t\|,$$

(20)

where in $(a)$ we use Assumptions 3.1 and 3.3. Now, we use (6d) to substitute $\bar{x}_t$ with its update within the last term of (20), and use Lemma 4.3 to bound
We obtain
\[
\|\tilde{s}_t - \tilde{m}_t\| \leq \beta_1 \|\tilde{s}_{t-1} - \tilde{m}_{t-1}\| + \frac{L}{\sqrt{N}} \|x_t - 1\bar{x}_t\| + \frac{L}{\sqrt{N}} \eta_{t-1} \\
+ \frac{L}{\sqrt{N}} \|1x_{t-1} - \alpha \tilde{d}_t - x_{t-1}\| \\
\leq \beta_1 \|\tilde{s}_{t-1} - \tilde{m}_{t-1}\| + \left(\sigma_W \frac{L}{\sqrt{N}} + \frac{L}{\sqrt{N}}\right) \|x_{t-1} - 1\bar{x}_{t-1}\| \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|m_{t-1} - 1\tilde{m}_{t-1}\| \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|s_{t-1} - 1\tilde{s}_{t-1}\| + \frac{L}{\sqrt{N}} \eta_{t-1} + \frac{\alpha L}{\sqrt{N} \epsilon} \|d_t\|, \\
\leq \beta_1 \|\tilde{s}_{t-1} - \tilde{m}_{t-1}\| + \left(\sigma_W \frac{L}{\sqrt{N}} + \frac{L}{\sqrt{N}}\right) \|x_{t-1} - 1\bar{x}_{t-1}\| \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|m_{t-1} - 1\tilde{m}_{t-1}\| \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|s_{t-1} - 1\tilde{s}_{t-1}\| + \frac{L}{\sqrt{N}} \eta_{t-1} + \frac{\alpha L}{\sqrt{N} \epsilon} \|\tilde{m}_t\|,
\]
where in (a) we use (18) to bound \(\tilde{d}_t\). By using Lemma 4.4 to bound \(\tilde{m}_t\) and by collecting the common terms involving \(\|x_{t-1} - 1\bar{x}_{t-1}\|\), we get
\[
\|\tilde{s}_t - \tilde{m}_t\| \leq \beta_1 \|\tilde{s}_{t-1} - \tilde{m}_{t-1}\| \\
+ \left(\sigma_W \frac{L}{\sqrt{N}} + \frac{L}{\sqrt{N}} + \frac{\alpha(1 - \beta_1)L^2}{\sqrt{N} \epsilon} \right) \|x_{t-1} - 1\bar{x}_{t-1}\| \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|m_{t-1} - 1\tilde{m}_{t-1}\| + \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|s_{t-1} - 1\tilde{s}_{t-1}\| + \frac{L}{\sqrt{N}} \eta_{t-1} \\
+ \frac{\alpha \beta_1 L}{\sqrt{N} \epsilon} \|\tilde{m}_{t-1}\| + \frac{\alpha(1 - \beta_1)L^2}{\sqrt{N} \epsilon} \|\bar{x}_{t-1} - x_{*,t-1}\|,
\]
thus concluding the proof. 

\[\square\]

**Lemma 4.7 (Solution error).** Let Assumptions 3.1, 3.2, 3.3 and 3.4 hold. Then, for all \(t \geq 1\), it holds
\[
\|\bar{x}_t - x_{*,t}\| \leq \phi \|\bar{x}_{t-1} - x_{*,t-1}\| + \frac{\alpha \beta_1 L}{\sqrt{N}} \|\tilde{s}_{t-1} - \tilde{m}_{t-1}\| + \frac{\alpha L}{\sqrt{N} \epsilon} \|x_{t-1} - 1\bar{x}_{t-1}\| + \zeta_t,
\]
where
\[
\phi \triangleq \max \left\{ \left| 1 - \frac{\alpha(1 - \beta_1)}{\sqrt{\epsilon + G}} \right|, \left| 1 - \frac{\alpha(1 - \beta_1)}{\sqrt{\epsilon}} L \right| \right\}.
\]
Proof. By using (6d), one has
\[ \| \bar{x}_t - x_{*,t} \| = \| \bar{x}_{t-1} - \alpha \bar{d}_t - x_{*,t} \| \]
\[ = \| \bar{x}_{t-1} - \alpha \bar{d}_t - x_{*,t-1} + x_{*,t-1} - x_{*,t} \| \]
\[ \leq \| \bar{x}_{t-1} - \alpha \bar{d}_t - x_{*,t-1} \| + \| x_{*,t-1} - x_{*,t} \| \]
\[ \leq \| \bar{x}_{t-1} - \alpha \bar{d}_t - x_{*,t-1} \| + \zeta, \]
in which (a) uses the triangle inequality and (b) uses Assumption 3.3. Now, we add and subtract within the norm the term
\[ \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) \]
and we use the triangle inequality to write
\[ \| \bar{x}_t - x_{*,t} \| \leq \| \bar{x}_{t-1} - \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) - x_{*,t-1} \| \]
\[ + \left\| \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) - \alpha \bar{d}_t \right\| + \zeta, \] (22)
Consider the second term of (22) and use (6c) to write
\[ \left\| \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) - \alpha \bar{d}_t \right\| \]
\[ = \left\| \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) - \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \right\| \]
\[ = \left\| \alpha 1^T(V_t + \epsilon I)^{-1/2}1 \left( \nabla f_{t-1}(1 \bar{x}_{t-1}) - m_t \right) \right\| \]
\[ \leq \left\| \alpha \frac{1^T(\epsilon I)^{-1/2}1}{N} \right\| \left( \nabla f_{t-1}(1 \bar{x}_{t-1}) - m_t \right) \],
where in (a) we use the fact that \((V_t + \epsilon I)^{-1/2} \leq \frac{1}{\sqrt{\epsilon}}\) for all \(t \geq 0\). Then
\[ \left\| \alpha \frac{1^T(V_t + \epsilon I)^{-1/2}1}{N} \nabla f_{t-1}(1 \bar{x}_{t-1}) - \alpha \bar{d}_t \right\| \]
\[ \leq \frac{\alpha}{\sqrt{\epsilon}} \left\| \frac{1^T}{N} \left( \nabla f_{t-1}(1 \bar{x}_{t-1}) - m_t \right) \right\| \]
\[ = \frac{\alpha}{\sqrt{\epsilon}} \left\| \nabla f_{t-1}(1 \bar{x}_{t-1}) - m_t \right\|. \] (23)
We add and subtract the term $\frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1})$ and then we use the triangle inequality to rewrite (23) as
\[
\frac{\alpha}{\sqrt{\epsilon}} \| \nabla f_{t-1}(\bar{x}_{t-1}) - \bar{m}_t \|
\]
\[
= \frac{\alpha}{\sqrt{\epsilon}} \left\| \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) - \bar{m}_t \right\| + \frac{\alpha}{\sqrt{\epsilon}} \left\| \nabla f_{t-1}(1 \bar{x}_{t-1}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \right\|
\]
\[
\leq \frac{\alpha}{\sqrt{\epsilon}} \left\| \nabla f_{t-1}(1 \bar{x}_{t-1}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \right\|
\]
\[
\leq \frac{\alpha}{\sqrt{\epsilon}} \left\| \beta_1 (\bar{s}_{t-1} - \bar{m}_{t-1}) \right\| + \frac{\alpha}{\sqrt{\epsilon}} \left\| \nabla f_{t-1}(1 \bar{x}_{t-1}) - \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1}) \right\|
\]
\[
\leq \frac{\alpha \beta_1}{\sqrt{\epsilon}} \| \bar{s}_{t-1} - \bar{m}_{t-1} \| + \frac{\alpha L}{\sqrt{\epsilon} \sqrt{N}} \| \bar{x}_{t-1} - \bar{x}_{t-1} \|,
\]
where in (a) we use (6a), (b) uses the relation $\bar{s}_{t-1} = \frac{1}{N} \sum_{i=1}^{N} \nabla f_{i,t-1}(x_{i,t-1})$, and (c) uses Assumption 3.1.

Next, in order to bound the right-hand side of (22), first notice that
\[
\frac{1}{\sqrt{G + \epsilon}} < \frac{1^T (V_t + \epsilon I)^{-1/2} 1}{N} < \frac{1}{\sqrt{\epsilon}}.
\]
Moreover $f_t$ is $q$-strongly convex with $L$-Lipschitz continuous gradient. Then, it is possible to apply Lemma A.2 to bound the first term in (22) as
\[
\left\| \bar{x}_{t-1} - \alpha (1 - \beta_1) \frac{1^T (V_t + \epsilon I)^{-1/2} 1}{N} \nabla f(1 \bar{x}_{t-1}) - x_{s,t-1} \right\|
\]
\[
\leq \max \left\{ \left| 1 - \frac{\alpha (1 - \beta_1)}{\sqrt{\epsilon} + G} q \right|, \left| 1 - \frac{\alpha (1 - \beta_1)}{\sqrt{\epsilon} L} \right| \right\} \| \bar{x}_{t-1} - x_{s,t-1} \|.
\]
Finally, by combining (24) and (25), it is possible to rewrite (22) as
\[
\| \bar{x}_t - x_{s,t} \| \leq \phi \| \bar{x}_{t-1} - x_{s,t-1} \| + \frac{\alpha \beta_1}{\sqrt{\epsilon}} \| \bar{s}_{t-1} - \bar{m}_{t-1} \| + \frac{\alpha L}{\sqrt{\epsilon} \sqrt{N}} \| \bar{x}_{t-1} - \bar{x}_{t-1} \| + \zeta_t,
\]
thus concluding the proof. \qed
4.2 Proof of Theorem 1

Let us start recalling that \( y_t \) is defined in (7) as

\[
y_t \triangleq \begin{bmatrix}
\| \tilde{m}_t \| \\
\| \tilde{s}_t - \bar{m}_t \| \\
\| \bar{m}_t - 1 \bar{m}_t \| \\
\| s_t - 1 \bar{s}_t \| \\
\| x_t - 1 \bar{x}_t \| \\
\| \bar{x}_t - x_{*t} \|
\end{bmatrix}.
\]

Combining Lemma 4.1, 4.2, 4.3, 4.4, 4.5, 4.7, it is possible to write

\[
y_t \leq A(\alpha)y_{t-1} + R_t,
\]

where

\[
A(\alpha) \triangleq \begin{bmatrix}
\beta_1 & 0 & 0 & 0 & (1 - \beta_1)B & (1 - \beta_1)L \\
\frac{\alpha \beta_1 B}{\sqrt{\epsilon}} & \beta_1 & \frac{\alpha \beta_1 B}{\sqrt{\epsilon}} & \frac{\alpha \beta_1 B}{\sqrt{\epsilon}} & K(\alpha) & \frac{(1 - \beta_1)BL}{\sqrt{\epsilon}} \\
0 & \beta_1 & 1 - \beta_1 & 0 & 0 & 0 \\
\frac{\alpha \beta_1 L \sqrt{N}}{\sqrt{\epsilon}} & 0 & \sigma_W + \frac{\alpha L (1 - \beta_1)}{\sqrt{\epsilon}} & \frac{\alpha (1 - \beta_1)L^2}{\sqrt{\epsilon}} & C + \frac{\alpha (1 - \beta_1)L^2 \sqrt{N}}{\sqrt{\epsilon}} & 0 \\
0 & \frac{\alpha \beta_1 L}{\sqrt{\epsilon}} & 0 & \frac{\alpha L (1 - \beta_1)}{\sqrt{\epsilon}} & \sigma_W & 0 \\
0 & \frac{\alpha \beta_1}{\sqrt{\epsilon}} & 0 & 0 & \frac{\alpha B}{\sqrt{\epsilon}} & \phi
\end{bmatrix},
\]

and

\[
R_t \triangleq \text{col} \left( 0, B\eta_{t-1}, 0, \sqrt{N}\eta_t, 0, \zeta_t \right)
\]

with

\[
B \triangleq \frac{L}{\sqrt{N}},
\]

\[
C \triangleq L\|W - I\|,
\]

\[
K(\alpha) \triangleq \frac{\sigma_W L}{\sqrt{N}} + \frac{\beta_1 L}{\sqrt{\epsilon N}} + \frac{\alpha \beta_1 (1 - \beta_1)L^2}{\sqrt{\epsilon}} = \sigma_W B + \beta_1 B + \frac{\alpha \beta_1 (1 - \beta_1)B^2}{\sqrt{\epsilon}}.
\]

Recall that \( \phi \) is defined (cf. (21)) as

\[
\phi \triangleq \max \left\{ \left| 1 - \frac{\alpha (1 - \beta_1)}{\sqrt{\epsilon + G}}q \right|, \left| 1 - \frac{\alpha (1 - \beta_1)}{\sqrt{\epsilon}} L \right| \right\}.
\]

If we take

\[
\alpha < \min \left\{ \frac{\sqrt{\epsilon + G}}{(1 - \beta_1)q}, \frac{\sqrt{\epsilon}}{(1 - \beta_1)L} \right\}
\]

then...
then it holds
\[ \phi = 1 - \alpha \delta \]
with
\[ \delta \triangleq \min \left\{ \frac{(1 - \beta_1)q}{\sqrt{\epsilon + G}}, \frac{(1 - \beta_1)L}{\sqrt{\epsilon}} \right\}. \]

From Assumption 3.3 it holds \( \eta_t \leq \eta \) and \( \zeta_t \leq \zeta \). Hence
\[ R_t \leq R \triangleq \text{col} \left( 0, B\eta, 0, \sqrt{N\eta}, 0, \zeta \right). \]

Now we decompose the matrix \( A(\alpha) \) defined in (26) in
\[ A(\alpha) \triangleq A_0 + \alpha E, \]
with
\[
A_0 \triangleq \begin{bmatrix}
\beta_1 & 0 & 0 & 0 & \beta_1 B & (1 - \beta_1)L \\
0 & \beta_1 & 0 & 0 & \sigma_W B + \beta_1 B & 0 \\
0 & 0 & \beta_1 & 1 - \beta_1 & 0 & 0 \\
0 & 0 & 0 & \sigma_W & C & 0 \\
0 & 0 & 0 & 0 & \sigma_W & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]
and
\[
E \triangleq \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
\frac{\beta_1 B}{\sqrt{\epsilon}} & 0 & \frac{\beta_1 B}{\sqrt{\epsilon}} & \frac{\beta_1 B}{\sqrt{\epsilon}} & \frac{\beta_1 (1 - \beta_1)B^2}{\sqrt{\epsilon}} & \frac{(1 - \beta_1)BL}{\sqrt{\epsilon}} \\
0 & 0 & 0 & 0 & 0 & 0 \\
\frac{\beta_1 L\sqrt{N}}{\sqrt{\epsilon}} & 0 & \frac{\beta_1 L}{\sqrt{\epsilon}} & \frac{(1 - \beta_1)L}{\sqrt{\epsilon}} & \frac{(1 - \beta_1)L^2}{\sqrt{\epsilon}} & \frac{(1 - \beta_1)L^2 \sqrt{N}}{\sqrt{\epsilon}} \\
0 & 0 & \frac{\beta_1}{\sqrt{\epsilon}} & 1 - \beta_1 & 0 & 0 \\
0 & \frac{\beta_1}{\sqrt{\epsilon}} & 0 & \frac{\beta_1}{\sqrt{\epsilon}} & -\delta
\end{bmatrix}.
\]

Begin \( A_0 \) triangular, it is easy to see that its spectral radius is 1 since both \( \beta_1 \) and \( \sigma_W \) are in \((0, 1)\). Denote by \( \lambda(\alpha) \) the eigenvalues of \( A(\alpha) \) as a function of \( \alpha \). Call \( w \) and \( v \) respectively the left and right eigenvectors of \( A_0 \) associated to the eigenvalue 1. It is easy to see that it holds
\[
w = \text{col} \left( 0, 0, 0, 0, 0, 1 \right),
\]
\[
v = \text{col} \left( L, 0, 0, 0, 0, 1 \right).
\]
Since the eigenvalue 1 is a simple eigenvalue of $A(0)$, from Lemma A.3 it holds
\[
\left. \frac{d\lambda}{d\alpha} \right|_{\lambda=1,\alpha=0} = \frac{w^\top E v}{w^\top v} = -\delta < 0
\]
and then, by continuity of eigenvalues with respect to the matrix entries, $\lambda(\alpha)$ is strictly less than 1 for sufficiently small $\alpha > 0$. Then it is always possible to find $\alpha > 0$ that keeps the remaining eigenvalues inside the unit circle. Since $y_t \geq 0$ for all $t$, it holds
\[
y_t \leq A(\alpha)y_{t-1} + R.
\]
Thus, since $A(\alpha)$ and $R$ have only non-negative entries one has
\[
y_t \leq A(\alpha)^t y_0 + \sum_{k=0}^{t-1} A(\alpha)^{t-1-k} R.
\]
Here the first term decreases linearly with rate $\rho(\alpha)$ (equal to the spectral radius of $A(\alpha)$), while the second one is bounded. In particular,
\[
\|y_t\| \leq \left\| A(\alpha)^t y_0 + \sum_{k=0}^{t-1} A(\alpha)^{t-1-k} R \right\|
\leq \|A(\alpha)^t y_0\| + \left\| \sum_{k=0}^{t-1} A(\alpha)^{t-1-k} R \right\|
\leq \rho(\alpha)^t \|y_0\| + \|R\| \sum_{k=0}^{t-1} \rho(\alpha)^{t-1-k}
\leq \rho(\alpha)^t \|y_0\| + \|R\| \frac{1 - \rho(\alpha)^t}{1 - \rho(\alpha)}
\leq \rho(\alpha)^t \|y_0\| + \frac{\|R\|}{1 - \rho(\alpha)}. \quad (27)
\]
By noting that
\[
\|\bar{x}_t - x_{*,t}\| \leq \|y_t\|, \quad (28)
\]
and by exploiting the Lipschitz continuity of the gradients of $f_t$, we have that
\[
f_t(\bar{x}_t) - f_t(x_{*,t}) \leq \frac{L}{2} \|\bar{x}_t - x_{*,t}\|^2. \quad (29)
\]
Combining (27), (28) and (29), we get
\[
 f_t(\bar{x}_t) - f_t(x_{\star,t}) \leq \frac{L^2}{2} \left( \rho(\alpha)^{2t} \|y_0\|^2 + 2\rho(\alpha)^t \| y_0 \| \| R \| + \frac{\| R \|^2}{1 - \rho(\alpha)} \right)
\]
thus concluding the proof.

5 Numerical experiments

In this section we consider three multi-agent distributed learning problems to show the effectiveness of GTAdam. The first scenario regards the computation of a linear classifier via a regularized logistic regression function for a set of points that change over time. The second scenario involves the localization of a moving target. The third example is a stochastic optimization problem arising in a distributed image classification task.

In all the examples, the parameters of GTAdam are chosen as \( \beta_1 = 0.9, \beta_2 = 0.999, \) and \( \epsilon = 10^{-8} \) and the agents in the network communicate according to an (undirected, connected) Erdős-Rényi graph with parameter 0.5. Moreover, we compare GTAdam with the gradient tracking distributed algorithm (GT) (cf. Algorithm 2 in Section 2), and the distributed gradient descent (DGD) (see [47]) that, from the perspective of the agent \( i \), is given by
\[
x_{i,t} = \sum_{j \in N_i} w_{ij} x_{j,t-1} - \alpha \nabla f_{i,t} \left( \sum_{j \in N_i} w_{ij} x_{j,t-1} \right).
\]

5.1 Distributed classification via logistic regression

Consider a network of agents that want to cooperatively train a linear classifier for a set of points in a given feature space. Each agent \( i \) is equipped with \( m_i \in \mathbb{N} \) points \( p_{i,1}, \ldots, p_{i,m_i} \in \mathbb{R}^d \) with binary labels \( l_{i,k} \in \{-1,1\} \) for all \( k \in \{1, \ldots, m_i\} \). The problem consists of building a linear classification model from the given points, also called training samples. In particular, we look for a separating hyperplane described by a pair \( (w, b) \in \mathbb{R}^d \times \mathbb{R} \) given by \( \{ p \in \mathbb{R}^d \mid w^\top p + b = 0 \} \). The optimal hyperplane \( (w_{\star}, b_{\star}) \) separates all points with \( l_{i,k} = -1 \) from all the points with \( l_{i,k} = 1 \), namely it must satisfy
\[
\begin{align*}
w_{\star}^\top p_{i,k} + b_{\star} &\geq 0 \quad \forall (i, k) \quad \text{such that} \quad l_{i,k} = 1 \\
w_{\star}^\top p_{i,k} + b_{\star} &< 0 \quad \forall (i, k) \quad \text{such that} \quad l_{i,k} = -1.
\end{align*}
\]
The classification problem can be posed as a minimization problem described by

\[
\minimize_{w,b} \sum_{i=1}^{N} \sum_{k=1}^{m_i} \log \left( 1 + e^{-l_{i,k}(w^T p_{i,k} + b)} \right) + \frac{C}{2} \left( \|w\|^2 + b^2 \right),
\]

(30)

where \( C > 0 \) is the so-called regularization parameter. Notice that the presence of the regularization makes the cost function strongly convex. We consider an online instance of the classification problem in which each point \( p_{i,k} \in \mathbb{R}^2 \) is not static but moves along a circle of radius \( r = 1 \) according to the following law

\[
p_{i,k}^t = p_{i,k}^c + r \begin{bmatrix} \cos(t/100) \\ \sin(t/100) \end{bmatrix},
\]

where \( p_{i,k}^c \in \mathbb{R}^2 \) represents the randomly generated center of the considered circle. We consider a network of \( N = 50 \) agents and pick \( m_i = 50 \) for all \( i \in \{1, \ldots, N\} \). We performed an experimental tuning to optimize the step-sizes to enhance the convergence properties of each algorithm. In particular, we selected \( \alpha = 0.1 \) for GTAdam, \( \alpha = 0.001 \) for GT and \( \alpha = 0.001 \) for DGD. We performed Monte Carlo simulations consisting of 100 trials. In Figure 1 we plot the average across the trials of the relative cost error, namely \( \frac{f_t(\bar{x}_t) - f_t(x^*_t)}{f_t(x^*_t)} \), with \( x^*_t \) being the minimum of \( f_t \) for all \( t \). The plot

![Figure 1: Distributed classification via logistic regression. Mean of the relative cost errors and 1-standard deviation band obtained with Monte Carlo simulations consisting of 100 trials in which each of the \( N = 50 \) agents is equipped with \( m = 100 \) points.](image)

highlights that GTAdam exhibits a faster convergence compared to the other two algorithms, and achieves a smaller tracking error at steady-state.
5.2 Distributed source localization in smart sensor networks

The estimation of the exact position of a source is a key task in several applications in multi-agent distributed estimation and learning. Here, we consider an online version of the static localization problem considered in [48, Section 4.2]. An acoustic source is positioned at an unknown and time-varying location $\theta_t \in \mathbb{R}^2$. A network of $N$ sensors is capable to measure an isotropic signal related to such location and aims at cooperatively estimating $\theta_t$. Each sensor is placed at a fixed location $c_i \in \mathbb{R}^2$ and takes, at each time instant, a noisy measurement according to an isotropic propagation model

$$\omega_{i,t} \triangleq \frac{A}{\|\theta_t - c_i\|^\gamma} + \epsilon_{i,t},$$

where $A$ is a positive scalar, $\gamma \geq 1$ describes the attenuation characteristics of the medium through which the acoustic signal propagates, and $\epsilon_{i,t}$ is a zero-mean Gaussian noise with variance $\sigma^2$. Having these measurements, each node $i$ at each time $t$ tries to solve a nonlinear least-squares online problem

$$\min_{\theta} \sum_{i=1}^{N} \left( \omega_{i,t} - \frac{A}{\|\theta - c_i\|^\gamma} \right)^2, \quad t \geq 0.$$

We consider a network of $N = 50$ agents randomly located according to a two-dimensional Gaussian distribution with zero mean and variance $a^2 I_2 = 100 I_2$. The agents want to track the location of a moving target which starts at a random location $\theta_0 \in \mathbb{R}^2$ generated according to the same distribution of the agents. The target moves along a circle of radius $r = 0.5$ according to the following law

$$\theta_t = \theta_c + r \begin{bmatrix} \cos(t/200) \\ \sin(t/200) \end{bmatrix},$$

where $\theta_c \in \mathbb{R}^2$ represents the randomly generated center of the considered circle. We pick $\gamma = 1$, $A = 100$ and a noise variance $\sigma^2 = 0.001$. We take $\alpha = 0.1$ for GTAdam, $\alpha = 0.01$ for GT and $\alpha = 0.01$ for DGD. In Figure 2, we compare the algorithm performance in terms of the (instantaneous) cost function evolution. Figure 3 shows that the best performance in terms of average dynamic regret is obtained by GTAdam. GTAdam seems to achieve a smaller error, moreover it goes down rapidly with respect to DGD and GT. We make these comparisons by considering $\theta_t$ as the optimal estimate associated to the iteration $t$, but it is worth noting that the actual optimal solution may be slightly different because of the presence of the noise $\epsilon_{i,t}$ which affects the measurement of each agent.
5.3 Distributed image classification via neural networks

In this final example, we consider an image classification problem in which \( N \) nodes have to cooperatively learn how to correctly classify images. For this experiment we picked the Fashion-MNIST dataset \([49]\) consisting of black-and-white 28×28-pixels images of clothes belonging to 10 different classes.

Each agent \( i \) is given a local dataset \( D_i = \{(p_{i,k}, y_{i,k})\}_{k=1}^{m_i} \) consisting of \( m_i \) images \( p_{i,k} \in \mathbb{R}^{28 \times 28} \) along with their associated label \( y_{i,k} \in \{1, \ldots, 10\} \). The goal of the agents is to learn the parameters \( \theta \) of a certain function \( h(p; \theta) \) such that \( h(p_{i,\ell}; \theta) \) will output the correct label for \( p_{i,\ell} \). The resulting optimization problem can be written as

\[
\min_{\theta} \frac{1}{N} \sum_{i=1}^{N} \frac{1}{m_i} \sum_{k=1}^{m_i} V(y_{i,k}, h(p_{i,k}, \theta)) + \frac{\lambda}{N} \|\theta\|_2^2,
\]

where \( V(\cdot) \) is the categorical cross-entropy loss, and \( \lambda > 0 \) is a regularization parameter. This is a stochastic optimization problem in which

\[
f_i(\theta \mid D_i) = \mathbb{E}_{D_i}[\ell_i(\theta)] = \frac{1}{m_i} \sum_{k=1}^{m_i} V(y_{i,k}, h(p_{i,k}, \theta)) + \frac{\lambda}{N} \|\theta\|_2^2.
\]

We represent \( h(\cdot) \) by a neural network with one hidden layer (with 300 units with ReLU activation function) and an output layer with 10 units. Moreover we pick \( N = 16 \) agents and associate each of them \( m_i = 3750 \) labeled images (for all \( i \)). We performed Monte Carlo simulations consisting of 100 trials.
with each lasting 10 epochs over the local datasets. Here, since $m_i = m_j$ for all $i, j$, an epoch consists of 3750 iterations. The results are reported in Figure 4 and Figure 5 in terms of the global training loss

$$f(\{\theta_{i,ep}, D_i\}) = \sum_{i=1}^{N} f_i(\theta_{i,ep} | D_i),$$

being $\theta_{i,ep}$ the value of the parameters of agent $i$ at the end of the epoch $ep$, and the average training accuracy

$$\psi(\{\theta_{i,ep}, D_i\}) = \frac{1}{N} \sum_{i=1}^{N} \psi_i(\theta_{i,ep} | D_i),$$

where $\psi_i(\theta_{i,ep} | D_i)$ is the accuracy if agent $i$ on its local dataset at the end of epoch $ep$. We tested all the algorithms by using the same step-size $\alpha = 0.001$, and also by picking a higher step-size $\alpha = 0.1$ for the DGD and the GT. As it can be appreciated from Figure 4 and Figure 5 in both cases GTAdam outperforms the other two algorithms, with a huge improvement (also in terms of standard deviation) when using the same step-size.

\(^1\)Notice that, thanks to the consensus protocol, asymptotically $\theta_i = \theta_j$ for all $i, j$. Thus the average accuracy, asymptotically coincides with the accuracy on the whole training dataset.
Figure 4: Distributed image classification. Mean and 3-standard deviation band of the training loss and the training accuracy.

Figure 5: Distributed image classification. Mean and 3-standard deviation band of the training loss and the training accuracy.
6 Conclusions

In this paper, we proposed GTAdam, a novel distributed optimization algorithm tailored for multi-agent online learning. Inspired by the popular (centralized) Adam algorithm, our novel (distributed) GTAdam is based on the gradient tracking distributed scheme which is enhanced with adaptive first and second order momentum estimates of the gradient. We provided theoretical bounds on the convergence of the proposed algorithm. Moreover, we tested GTAdam in three different application scenarios showing an improvement of the performance compared with the current state-of-the-art algorithms.

A Appendix

Lemma A.1. Let $f(x) : \mathbb{R}^n \to \mathbb{R}$ be $\sigma$-strongly convex and with $L$-Lipschitz continuous gradient. Moreover, let $D \in \mathbb{R}^{n \times n}$ be positive definite diagonal matrix such that $D_{ii} \in [\epsilon, M]$ for all $i = 1, \ldots, n$ with $M \geq \epsilon > 0$ and $M < \infty$. Let $\bar{L} = ML$ and $\bar{\sigma} = \epsilon \sigma$. Then,

\[ \langle D \nabla f(x) - D \nabla f(y), x - y \rangle \geq \frac{\bar{\sigma} \bar{L}}{\bar{\sigma} + L} \|x - y\|^2 + \frac{1}{\bar{\sigma} + L} \|D \nabla f(x) - D \nabla f(y)\|^2 \]

Proof. Let $h(x)$ be a function such that $\nabla h(x) = D \nabla f(x)$ for all $x$. It can be easily shown that $h$ has $\bar{L}$-Lipschitz continuous gradients, in fact

\[ \|\nabla h(x) - \nabla h(y)\| = \|D \nabla f(x) - D \nabla f(y)\| \]

\[ \leq \|D\| \|\nabla f(x) - \nabla f(y)\| \]

\[ \leq \|D\| \|L\| \|x - y\| \]

\[ \leq ML \|x - y\| \]

Moreover $h$ is $\bar{\sigma}$-strongly convex, since $\nabla^2 h(x) = D \nabla^2 f(x) \succeq D \sigma I \geq \epsilon \sigma I$.

Define $g(x) = h(x) - \frac{\sigma}{2} \|x\|^2$. Notice that, by definition, $g$ is convex and with $(\bar{L} - \bar{\sigma})$-Lipschitz continuous gradient. Thus, by definition we have

\[ \langle \nabla g(x) - \nabla g(y), x - y \rangle \geq \frac{1}{L - \bar{\sigma}} \|\nabla g(x) - \nabla g(y)\|^2 \quad (31) \]

Now, by using the definition of $g$ one has

\[ \langle \nabla h(x) - \bar{\sigma} x - \nabla h(y) + \bar{\sigma} y, x - y \rangle = \langle \nabla h(x) - \nabla h(y), x - y \rangle - \bar{\sigma} \|x - y\|^2 \quad (32) \]
Moreover
\[
\|\nabla g(x) - \nabla g(y)\|^2 = \|\nabla h(x) - \bar{\sigma} x - \nabla h(y) + \bar{\sigma} y\|^2
= \|\nabla h(x) - \nabla h(y)\|^2 + \bar{\sigma}^2 \|x - y\|^2 - 2\bar{\sigma} \langle \nabla h(x) - \nabla h(y), x - y \rangle
\] (33)

By combining (31), (32), and (33) we get
\[
\langle \nabla h(x) - \nabla h(y), x - y \rangle \geq \frac{\bar{\sigma} L}{\sigma + L} \|x - y\|^2 + \frac{1}{\sigma + L} \|\nabla h(x) - \nabla h(y)\|^2
\]
The proof is completed by using \(\nabla h(x) = Df(x)\).

\[\square\]

**Lemma A.2.** Let the assumptions of Lemma A.1 hold. Moreover, let
\[
x_t = x_{t-1} - \alpha Df(x_{t-1})
\]
with \(\alpha \in (0, \frac{2}{L})\). Then,
\[
\|x_t - x_*\|^2 \leq \max\{(1 - \alpha \bar{\sigma})^2, (1 - \alpha \bar{L})^2\} \|x_{t-1} - x_*\|^2
\]

**Proof.** By using the update rule, one has
\[
\|x_t - x_*\|^2 = \|x_{t-1} - \alpha Df(x_{t-1}) - x_*\|^2
= \|x_{t-1} - x_*\|^2 - 2\alpha \langle Df(x_{t-1}), x_{t-1} - x_* \rangle + \alpha^2 \|Df(x_{t-1})\|^2
= \|x_{t-1} - x_*\|^2 - 2\alpha \langle Df(x_{t-1}) - Df(x_*), x_{t-1} - x_* \rangle
+ \alpha^2 \|Df(x_{t-1}) - Df(x_*)\|^2
\]

Now, by using Lemma A.1 we have
\[
\|x_t - x_*\|^2 \leq \|x_{t-1} - x_*\|^2 + \alpha^2 \|Df(x_{t-1}) - Df(x_*)\|^2
- 2\alpha \frac{\bar{\sigma} L}{\sigma + L} \|x_{t-1} - x_*\|^2 - \frac{2\alpha}{\sigma + L} \|Df(x_{t-1}) - Df(x_*)\|^2
= \left(1 - 2\alpha \frac{\bar{\sigma} L}{\bar{\sigma} + L}\right) \|x_{t-1} - x_*\|^2
+ \alpha \left(\alpha - \frac{2}{\sigma + L}\right) \|Df(x_{t-1}) - Df(x_*)\|^2
\leq \left(1 - 2\alpha \frac{\bar{\sigma} L}{\bar{\sigma} + L}\right) \|x_{t-1} - x_*\|^2 + \alpha \left(\alpha \bar{L}^2 - \frac{2\bar{\sigma}^2}{\bar{\sigma} + L}\right) \|x_{t-1} - x_*\|^2
= \left(1 - 2\alpha \frac{\bar{\sigma}(\bar{\sigma} + L)}{\bar{\sigma} + L} + \alpha^2 \bar{L}^2\right) \|x_{t-1} - x_*\|^2
= \left(1 - 2\alpha \bar{\sigma} + \alpha^2 \bar{L}^2\right) \|x_{t-1} - x_*\|^2
\leq \max\{(1 - \alpha \bar{\sigma})^2, (1 - \alpha \bar{L})^2\} \|x_{t-1} - x_*\|^2
\]

30
thus concluding the proof.

Notice that the previous Lemma also implies that

$$
\|x_t - x^\star\| \leq \max\{|1 - \alpha \tilde{\sigma}|, |1 - \alpha \tilde{L}|\}\|x_{t-1} - x^\star\|.
$$

**Lemma A.3.** Let $A_0, E \in \mathbb{R}^{n \times n}$ and let $\lambda$ be a simple eigenvalue of $A_0$. Let $v$ and $w$ be, respectively, the right and left eigenvectors of $A_0$ corresponding to the eigenvalue $\lambda$. Then, for each $\epsilon > 0$, there exists a $\delta > 0$ such that, for all $\alpha \in \mathbb{R}$ with $|\alpha| < \delta$, there is a unique eigenvalue $\lambda(\alpha)$ of $A_0 + \alpha E$ such that

$$
\left|\lambda(\alpha) - \alpha \frac{w^H E v}{w^H v}\right| \leq |\alpha|,
$$

in which $w^H$ denotes the Hermitian of $w$. Moreover $\lambda(\alpha)$ is continuous at $\alpha = 0$ and

$$
\lim_{\alpha \to 0} \lambda(\alpha) = \lambda.
$$

Moreover $\lambda(\alpha)$ is differentiable at $\alpha = 0$ and it holds

$$
\frac{d\lambda(\alpha)}{d\alpha}\bigg|_{\alpha=0} = \frac{w^H E v}{w^H v}.
$$

**Proof.** See [50] Theorem 6.3.12.
