Unification of Rare/Weak Detection Models using Moderate Deviations Analysis and Log-Chisquared P-values

Alon Kipniskipnisal@stanford.edu

1Department of Statistics, Stanford University

Abstract:
Rare/Weak models for multiple hypothesis testing assume that only a small proportion of the tested hypotheses concern non-null effects and the individual effects are only moderately large, so that they generally do not stand out individually, for example in a Bonferroni analysis.

Such rare/weak models have been studied in quite a few settings, for example in some cases studies focused on underlying Gaussian means model for the hypotheses being tested; in some others, Poisson. It seems not to have been noticed before that such seemingly different models have asymptotically the following common structure: Summarizing the evidence each test provides by the negative logarithm of its P-value, previous rare/weak model settings are asymptotically equivalent to detection where most negative log P-values have a standard exponential distribution but a small fraction of the P-values might possibly have an alternative distribution which is moderately larger; we do not know which individual tests those might be, or even if there are any such. Moreover, the alternative distribution is noncentral chisquared on one degree of freedom.

We characterize the asymptotic performance of global tests combining these P-values in terms of the chisquared mixture parameters: the scaling parameters controlling heteroscedasticity, the non-centrality parameter describing the effect size whenever it exists, and the parameter controlling the rarity of the non-null effects. Specifically, in a phase space involving the last two parameters, we derive a region where all tests are asymptotically powerless. Outside of this region, the Berk-Jones and the Higher Criticism tests have maximal power. Inference techniques based on the minimal P-value, false-discovery rate controlling, and Fisher’s combination test have sub-optimal asymptotic phase diagrams. We provide various examples for multiple testing problems of the said common structure.

Our log-chisquared approximation for P-values is different from Bahadur’s log-normal approximation; the log-normal approximation is a large deviations phenomenon, while the effects we study appear instead on the moderate deviations scale. The log-normal approximation would be unsuitable for understanding Rare/Weak multiple testing models.

Keywords and phrases: hypothesis testing, multiple testing, P-value, heterogeneous mixture, heteroscedastic mixture, higher criticism, false discovery rate, Berk-Jones.

1. Introduction

Consider multiple hypothesis testing situation, each test involves a different feature of the data where different features are independent. We are interested
in testing a global null hypothesis against the following alternative: the non-null effects are concentrated in a small, but unknown, subset of the hypotheses. In the most challenging situation, effects are not only rare but also weak in the sense that the non-null test statistics are unlikely to provide evidence after Bonferroni correction. Rare/weak multiple hypothesis testing problems of this nature arise frequently in modern statistics and comprise a wide range of application [19]. Specific examples include:

- **Sparse signal detection.** Suppose we are interested in intercepting a transmission that occupies few frequency bands out of potentially many, while the occupied bands are unknown to us [51]. The set of features are periodogram ordinates associated with individual frequency bands. Evidence for the presence of a signal can be gathered by testing each periodogram ordinate against the same exponential distribution.

- **Classification.** Classifying images or other high-dimensional signals frequently involves thousands or more features. We think about the typical response in each feature under a specific base class as the global null hypothesis. Testing against this null amounts to determining whether the tested signal is associated with the base class or not. A situation of wide interest is when inter-class discrimination is due to a small proportion of features out of potentially many, and we do not know which ones they are likely to be. [18]

- **Detecting changes from a reference dataset.** Testing whether two high-dimensional datasets are simply two different realizations of the same data generating mechanism is a classical problem in statistics, computer science, and information theory [7, 2, 20]. This scenario is formulated as a two-sample testing problem; the null hypothesis states that both samples were obtained from the same high-dimensional parent distribution.

Applications as above and many others have motivated a significant body of work in rare/weak multiple testing settings through the past two decades, providing fruitful insights for signal detection, feature selection, and classification problems in high dimensions [35]. Specific examples of rare/weak multiple testing setting include normal mixtures [32, 34, 17, 1], binomial mixtures [43], linear regression model under Gaussian noise [3, 33], Poisson mixtures [4], heteroscedastic normal mixtures [11], general mixtures [12, 5], mixture of unknown distributions [14, 15, 5], and several two-sample settings [20].

In this paper, we study one rare/weak multiple testing setting that subsumes the vast majority of these previously studied ones. Our setting is not tied to a specific data-generating model. Instead, we model the behavior of a collection of P-values, each P-value summarizes the evidence of one test statistic against the global null. These P-values may be obtained either from one- or two-sample tests, and may represent responses over a variety of models. More generally, advantages of modeling the distribution of the P-values rather than the data are discussed in [36, 37, 48, 10].

In our setting, the $i$-th test statistic yields the P-value $p_i$, for $i = 1, \ldots, n$. We further suppose that $p_i \sim \text{Unif}(0, 1)$ under the global null, corresponding to the
case where the model underlying the $i$-th test statistics has a continuous distribution. Consequently, $-2 \log(p_i) \sim \text{Exp}(2)$, where Exp(2) is the exponential distribution with mean 2, aka as the chisquared distribution with two degrees of freedom $\chi^2_2$. Our model proposes the following alternative: Roughly $n\epsilon$ of the P-values depart from their uniform distribution and instead obey

$$-2 \log(p_i) \overset{D}{\approx} (\mu + \sigma Z)^2, \quad Z \sim N(0, 1).$$

(1)

Here $\overset{D}{\approx}$ indicates a specific form of approximation in distribution that we formalize in Section 1.1 below. Leaving the details of this approximation aside for now, (1) says that $-2 \log(p_i)$ is approximately distributed as a scaled noncentral chisquared random variable (RV) over one degree of freedom with noncentrality parameter $\mu$, and scaling parameter $\sigma$. We focus on the case where the rarity parameter $\epsilon$ vanishes while the intensity parameter $\mu$ is only moderately large, making our global testing problem challenging; in some cases, impossible. As we shall see, in this regime the non-null effects are not only rare but they are also weak in the sense that they generally do not stand out individually in a Bonferroni analysis.

A key insight of our analysis says that the log-chisquared approximation (1) is asymptotically accurate for characterizing the moderate-deviations behavior of the involved statistics [47] [16, Ch. 3.7]. Consequently, this approximation can be used to analyze the asymptotic power of tests in all previously studied settings in which moderate deviations analysis applies [17, 11, 15, 3, 12, 4, 43, 20], allowing the study of these models under a unified setting we denote as the Rare Moderate Departures model.

The emergence of the log-chisquared approximation for P-values under the rare/weak multiple testing setting is somewhat surprising, as this approximation is different than the classical log-normal approximation of Bahadur [6, 25] and Lambert and Hall [37]. In Section 3, we show that the log-normal approximation does not indicate the correct asymptotic performance of tests under our model. To summarize this last point, we establish here that a rare/weak multiple hypothesis testing setting in which the departures are on the moderate-deviations scale corresponds to detecting against exponential backgrounds few chisquared signals rather than few normal signals as one might have proposed in view of Bahadur’s approximation.

We also note that the logarithmic scoring scale for P-values is interesting on its own right. This scale goes back to Fisher, who initially suggested it as a method of ranking success in card guessing games [22]. For global testing, Fisher proposed the statistic [24]

$$F_n \equiv \sum_{i=1}^{n} -2 \log(p_i),$$

(2)

which has a $\chi^2_{2n}$ distribution under $H_0$. A test based on $F_n$ is known to be effective in the presence of small effects distributed across the bulk of cases, but not effective under relatively rare and somewhat stronger but individually
still weak as our model proposes. A formal statement of the inadequacy of $F_n$ in our setting is provided in Theorem 1.6 below. The logarithmic scale for P-values is now standard in genome-wide association studies (GWAS) [8, 44, 45] and other areas [39, 46]. Our setting provides an explicit model for testing rare/weak effects in these applications: testing chisquared departures against an exponential background. A similar model arise in detecting the presence of rare/weak sinusoids in white noise based on the periodogram. For this setting, Fisher’s periodogram test is based on the largest periodogram ordinate [23] which is analogous to a Bonferroni analysis.

1.1. Rare Moderate Departures Setting

The description above depict the following global hypothesis testing setting.

\[
\begin{align*}
H_0 & : -2 \log(p_i) \sim \text{Exp}(2), \quad i = 1, \ldots, n, \\
H_1^{(n)} & : -2 \log(p_i) \sim (1 - \epsilon)\text{Exp}(2) + \epsilon Q_i^{(n)}, \quad i = 1, \ldots, n,
\end{align*}
\]

where $Q_i^{(n)}$ is a probability distribution specifying the non-null behavior of the $i$-th P-value.

We calibrate the rarity parameter $\epsilon$ to $n$ according to

\[
\epsilon = \epsilon_n \equiv n^{-\beta},
\]

where $\beta \in (0, 1)$. This calibration proposes that, for an overwhelming majority of the tests, the response is indistinguishable under the null and alternative.

We compare $Q_i^{(n)}$ to the non-central and scaled chisquared distribution as in the right-hand side of (1), where the scaling parameter $\sigma$ is fixed and the non-centrality parameter $\mu$ is calibrated to $n$ as in:

\[
\mu = \mu_n(r) \equiv \sqrt{2r \log(n)}.
\]

Specifically, define the moderately perturbed scaled chisquared distribution

\[
\chi^2(r, \sigma) \overset{D}{=} (\mu_n(r) + \sigma Z)^2, \quad Z \sim \mathcal{N}(0,1),
\]

where $\overset{D}{=} \text{indicates equality in distribution. For the sake of formalizing the approximation in (1), we assume that } Q_i^{(n)} \text{ has density and introduce the following form of asymptotic equivalence between the densities of } Q_i^{(n)} \text{ and } \chi^2(r, \sigma).

\[
\lim_{n \to \infty} \frac{1}{\log(n)} \max_{i=1,\ldots,n} \log \left( \frac{dQ_i^{(n)}}{d\chi^2(r, \sigma)}(q \log(n)) \right) = 0, \quad q > 0.
\]

In words, (7) says that the log-likelihood ratio between $Q_i^{(n)}$ and the moderately perturbed chisquared distribution $\chi^2(r, \sigma)$ grows at most sub-logarithmically.
uniformly over all coordinates. Henceforth, we refer to hypothesis testing problems of the form (3) under the condition (7) as the Rare Moderate Departures (RMD) model with log-chisquared parameters \((r, \sigma)\).

A useful criterion for the validity of (7) is
\[
Q_i^{(n)} \sim D (\mu_n(r) + \sigma Z)^2 (1 + o_p(1)) , \quad n \to \infty ,
\]
where \(o_p(1)\) indicates a sequence of RVs tending to zero in probability uniformly in \(i\) as \(n \to \infty\).

1.2. Asymptotic P-values and Randomization

In situations where it is infeasible to obtain exact P-values, we can extend the RMD setting of (3) by considering
\[
\begin{align*}
H_0^{(n)} & : -2 \log(p_i) \sim E_i^{(n)} , \quad i = 1, \ldots, n , \\
H_1^{(n)} & : -2 \log(p_i) \sim (1 - \epsilon) E_i^{(n)} + \epsilon Q_i^{(n)} , \quad i = 1, \ldots, n ,
\end{align*}
\]
where \(Q_i^{(n)}\) satisfies (7) and the probability distribution \(E_i^{(n)}\) converges to \(\text{Exp}(2)\) or, equivalently, \(p_i \sim D \text{ Unif}(0, 1)\). In the context of this paper, there is no difference in the properties of the model (3) compared to (9).

Our RMD model formulation does not directly apply when the distributions of underlying test statistics associated with some \(p_i\) are discrete. Nevertheless, we may incorporate cases of this form by following a standard optimal decision theory practice and consider randomized P-values whose distribution under the null is uniform while its distribution is stochastically dominated by \(p_i\) \([29]\).

1.3. Asymptotic Power and Phase Transition

RMD models experience a phase transition phenomenon in the following sense: for some choice of the parameters \(r, \beta, \) and \(\sigma\), the two hypothesis are completely indistinguishable. In another region, some tests can asymptotically distinguish \(H_1^{(n)}\) from \(H_0\) with probability tending to one.

Formally, for a given sequence of statistics \(\{T_n\}_{n=1}^{\infty}\), we say that \(\{T_n\}_{n=1}^{\infty}\) is asymptotically powerful if there exists a sequence of thresholds \(\{h_n\}_{n=1}^{\infty}\) such that
\[
\Pr_{H_0}(T_n < h_n) + \Pr_{H_1^{(n)}}(T_n \leq h_n) \to 0 ,
\]
as \(n\) goes to infinity. In contrast, we say that \(\{T_n\}_{n=1}^{\infty}\) is asymptotically powerless if
\[
\Pr_{H_0}(T_n < h_n) + \Pr_{H_1^{(n)}}(T_n \leq h_n) \to 1 ,
\]
for any sequence \(\{h_n\}_{n \in \mathbb{N}}\). The so-called phase transition curve is the boundary of the region in the parameter space \((\beta, r)\) in which all tests are asymptotically powerless.
Unification of Rare/Weak Detection Models

Fig 1. Phase Diagram. The phase transition curve $\rho(\beta; \sigma)$ of (10) defines the detection boundary under the Rare Moderate Departure model (3). For $r < \rho(\beta; \sigma)$, all tests are asymptotically powerless. For $r > \rho(\beta; \sigma)$, some tests, including Higher Criticism and the Berk-Johns, are asymptotically powerful.

Define the would-be phase transition curve

$$
\rho(\beta; \sigma) \equiv \begin{cases} 
(2 - \sigma^2)(\beta - 1/2) & \frac{1}{2} < \beta < 1 - \frac{\sigma^2}{4}, \quad 0 < \sigma^2 < 2 \\
(1 - \sigma \sqrt{1 - \beta})^2 & 1 - \frac{\sigma^2}{4} \leq \beta < 1, \quad 0 < \sigma^2 < 2, \\
0 & \frac{1}{2} < \beta < 1 - \frac{1}{\sigma}, \quad \sigma^2 \geq 2 \\
(1 - \sigma \sqrt{1 - \beta})^2 & 1 - \frac{1}{\sigma} \leq \beta < 1, \quad \sigma^2 \geq 2.
\end{cases}
$$

One side of the phase transition characterization is provided as follows.

**Theorem 1.1.** Consider the hypothesis testing problem (3) and suppose that (7) holds. If $r < \rho(\beta; \sigma)$, all tests are asymptotically powerless.

The function $\rho(\beta; \sigma)$ was first derived in [11] to describe the detection boundary of rare/weak heteroscedastic normal means; see the discussion in Section 3.2 below. Theorems 1.1 extends this result from [11] to any rare/weak multiple testing model falling under our RMD formulation, several of which we discuss in Section 2 below. Figure 1, adapted from [11], depicts $\rho(\beta; \sigma)$ for several choices of $\sigma$.

**1.4. Optimal Tests**

To complete the phase transition characterization of RMD models initiated in Theorem 1.1, we consider two tests that are asymptotically powerful whenever $r > \rho(\beta; \sigma)$.
1.4.1. The Higher Criticism Test

The Higher Criticism (HC) of the P-values $p_1, \ldots, p_n$ is defined as [17]

$$HC^*_n \equiv \max_{1 \leq i \leq n} \sqrt{n} \frac{i/n - p(i)}{\sqrt{p(i)(1 - p(i))}}.$$  \[17\]

where $p(i)$ is the $i$-th order statistic of $\{p_i, i = 1, \ldots, n\}$, and $0 < \gamma_0 < 1$ is a tunable parameter that has no effect on the asymptotic value of $HC^*_n$. The HC test rejects $H_0^{(n)}$ for large values of $HC^*_n$.

**Theorem 1.2.** Consider the hypothesis testing problem (3) and suppose that (7) holds. If $r > \rho(\beta; \sigma)$, then $HC^*_n$ is asymptotically powerful.

1.4.2. The Berk-Jones Test

Define the P-values

$$\pi_i \equiv \Pr(\text{Beta}(i, n - i + 1) < p(i)), \quad i = 1, \ldots, n,$$

where $\text{Beta}(a, b)$ is the Beta distribution with shape parameters $a, b > 0$. The Berk-Jones (BJ) test statistic is defined as [9]

$$M_n \equiv \min\{M_n^-, M_n^+\}, \quad M_n^- \equiv \min_i \pi_i, \quad M_n^+ \equiv \min_i (1 - \pi_i).$$

**Theorem 1.3.** Consider the hypothesis testing problem (3) and suppose that (7) holds. If $r > \rho(\beta; \sigma)$, then $M_n$ is asymptotically powerful.

1.5. Sub-optimal Tests

1.5.1. Bonferroni and false-discovery rate controlling

Bonferroni and false-discovery rate (FDR) controlling methods are two popular approaches to multiple testing inference procedures [21]. Starting with the P-values $p_1, \ldots, p_n$, Bonferroni type inference uses the minimal P-value $p(1)$ as the test statistics. One rule for FDR controlling selection with control parameter $q$ uses the minimal $k^*$ P-values such that $k^*$ is the largest integer $k$ satisfying $p(k) \leq qk/n$, hence a test based on $p(1), \ldots, p(k^*)$ at the level $\alpha$ takes the form

$$\text{Reject } H_0 \text{ if and only if } \min_{1 \leq i \leq n} \frac{p(i)}{i/n} \leq h(\alpha, n),$$  \[11\]

where $h(\alpha, n) < 1$ is a critical value designed to reject $H_0$ with probability at most $\alpha$ under $H_0$. 
For an RMD model, both procedures turn out to be asymptotically powerful (respectively, powerless) within the exact same region. The phase transition curve distinguishing powerfulness from powerlessness is given by

\[ \rho_{\text{Bonf}}(\beta; \sigma) = \begin{cases} 
(1 - \sigma \sqrt{1 - \beta})^2, & 1/2 < \beta < 1, \quad \sigma^2 < 2, \\
(1 - \sigma \sqrt{1 - \beta})^2, & 1 - \frac{1}{\sigma^2} \leq \beta < 1, \quad \sigma^2 > 2, \\
0, & \beta < 1 - \frac{1}{\sigma^2}, \quad \sigma^2 > 2.
\] (12)

**Theorem 1.4.** Consider the hypothesis testing problem (3) and suppose that (7) holds. \( T_n^{\text{Bonf}} = -\log(p(i)) \) is asymptotically powerless whenever \( r < \rho_{\text{Bonf}}(\beta; \sigma) \) and asymptotically powerful whenever \( r > \rho_{\text{Bonf}}(\beta; \sigma) \).

**Theorem 1.5.** Consider the hypothesis testing problem (3) and suppose that (7) holds. A test based on (11) is asymptotically powerless whenever \( r < \rho_{\text{Bonf}}(\beta; \sigma) \) and asymptotically powerful whenever \( r > \rho_{\text{Bonf}}(\beta; \sigma) \).

Theorems 1.4 and 1.5 imply that both Bonferroni and FDR type inference are asymptotically optimal only when \( \beta > (7 - \sigma^2)/8 \). This situation is similar to the case of the Gaussian means model studied in [17], implying that under moderate rarity the evidence for discriminating \( H_0^{(n)} \) from \( H_1^{(n)} \) are not amongst sets of the form \( \{p_i : p_i < qk/n, q \in (0,1) \} \). Asymptotically, optimal discrimination is achieved by considering P-values in the much wider range \( \{p_i : p_i < n^{-(1-\delta)}\} \) for some \( \delta > 0 \). This range is considered by HC and BJ, but not by FDR or Bonferroni.

### 1.5.2. Fisher’s Combination Test

We conclude this section by noting that Fisher’s combination test (2) is asymptotically powerless in our setting.

**Theorem 1.6.** Consider the hypothesis testing problem (3) and suppose that (7) holds. A test based on \( F_n \) of (2) is asymptotically powerless whenever \( \beta > 1/2 \).

### 1.6. Structure of this paper

In Section 2 we explore several rare/weak signal detection problems that conform to the RMD model formulation. Therefore, the asymptotic characterizations of global testing in these models provided by Theorems 1.1-1.6 apply. A detailed discussion regarding the underlying log-chisquared approximation of P-values and other properties is provided in Section 3. The proofs of Theorems 1.1-1.6 are in Section 4.

### 2. Examples of Rare/Weak Moderate Departures Models

We consider below various examples of rare/weak multiple testing settings that are carried under our RMD formulation. In most cases, these settings were previously studied, however, without the RMD formulation and without establishing
all RMD model properties in Theorems 1.1-1.6. We note these earlier studies at the end of each example.

2.1. Normal Means

Consider the hypothesis testing problem
\[
\begin{align*}
H_0 & : X_i \sim \mathcal{N}(0, 1), \quad \forall i = 1, \ldots, n \\
H_1 & : X_i \sim (1 - \epsilon)\mathcal{N}(0, 1) + \epsilon\mathcal{N}(\mu, \sigma^2), \quad \forall i = 1, \ldots, n.
\end{align*}
\] (13)

The relation between the model (13) to (3) is via the z-tests
\[
p_i = \bar{\Phi}(X_i), \quad \bar{\Phi}(x) \equiv \Pr(\mathcal{N}(0, 1) > x), \quad i = 1, \ldots, n.
\] (14)

Standard facts about Mills’ ratio (see, e.g., [28]) imply
\[
-2 \log(\bar{\Phi}(x)) \sim -2 \log\left(\frac{\phi(x)}{|x|}\right) = x^2(1 + o(1)),
\] (15)
as \(x \to \infty\). Consequently, under \(H_1^{(n)}\), the distribution of \(-2 \log(p_i)\) is of the form
\[
(1 - \epsilon)\text{Exp}(2) + \epsilon Q^{(n)}_i,
\]
where \(Q^{(n)}_i\) is a probability distribution obeying
\[
Q^{(n)}_i \overset{D}{=} (\sigma Z + \mu)^2(1 + o_p(1)), \quad Z \sim \mathcal{N}(0, 1),
\] (16)
as \(\mu \to \infty\). For \(\mu = \mu_n(r)\), the last evaluation immediately implies that \(Q^{(n)}_i\) satisfies (7) hence the P-values of (14) corresponds to a RMD model with log-chisquared parameters \((r, \sigma)\).

We note that Cai, Jeng, and Jin studied the setting (13) in [11]. They derived the optimal phase transition curve \(\rho(\beta; \sigma)\) and showed that it is attained by HC of the P-values (14). The case where \(\sigma^2 = 1\) was initially studied in [32, 34, 17]; the counterparts of Theorems 1.1-1.6 for this case are provided in [17].

2.2. Two-Sample Normal Means

A two-sample version of (13) takes the form:
\[
\begin{align*}
H_0 & : X_i, Y_i \sim \mathcal{N}(\nu_i, 1), \quad i = 1, \ldots, n, \\
H_1^{(n)} & : \begin{cases} 
X_i \sim \mathcal{N}(\nu_i, 1), \\
Y_i \sim (1 - \epsilon)\mathcal{N}(0, 1) + \epsilon\mathcal{N}(\nu_i + \mu, \sigma^2)
\end{cases}, \quad i = 1, \ldots, n.
\end{align*}
\] (17)

where \(\nu_1, \ldots, \nu_n\) is a sequence of unknown means. For this problem, consider the P-values
\[
p_i = \bar{\Phi}\left(\frac{|Y_i - X_i|}{\sqrt{2}}\right).
\] (18)
Notice that, with \( \tilde{Y}_i \sim \mathcal{N}(\nu_i + \mu, \sigma^2) \) and \( X_i \sim \mathcal{N}(\nu_i, 1) \), Mills’ ratio (15) implies
\[
-2 \log \left( \Phi \left( \sqrt{\frac{1}{2}} \tilde{Y}_i - \frac{X_i}{\sqrt{2}} \right) \right) \equiv \left( \sqrt{\frac{1}{2}} \frac{1 + \sigma^2}{\sigma} Z + \frac{\mu}{\sqrt{2}} \right)^2 (1 + o_p(1)), \quad Z \sim \mathcal{N}(0, 1),
\]
as \( \mu \to \infty \). Therefore, under \( H_1^{(n)} \) we have that the distribution of \(-2 \log(p_i)\) is of the form
\[
(1 - \epsilon)\text{Exp}(2) + \epsilon Q_i^{(n)},
\]
where, \( Q_i^{(n)} \) is a probability distribution obeying
\[
Q_i^{(n)} \overset{D}{=} \left( \sqrt{\frac{1}{2}} \frac{1 + \sigma^2}{\sigma} Z + \frac{\mu}{\sqrt{2}} \right)^2 (1 + o_p(1)), \quad Z \sim \mathcal{N}(0, 1),
\]
as \( \mu \to \infty \). It follows that with \( \mu \) calibrated to \( n \) as in (5), \( Q_i^{(n)} \) satisfies (7) with mean parameter \( \mu'_r(r) = \mu_n(r) / \sqrt{2} = \sqrt{r \log(n)} \) and scaling parameter \( \sigma' = \sqrt{(1 + \sigma^2) / 2} \), hence the P-values (18) corresponds to a RMD model with log-chisquared parameters \( (r / 2, \sigma') \).

In order to derive a phase transition curve for this model, we start from (10), adjusting for the factor 2 scaling in the non-centrality parameter compared to (5), and substituting \( \sqrt{(1 + \sigma^2) / 2} \) for the standard deviation. We obtain:
\[
\rho_{\text{two-sample}}(\beta; \sigma) = \begin{cases} 
(3 - \sigma^2)(\beta - 1/2) & \frac{1}{2} < \beta < \frac{7 - \sigma^2}{8}, \\ 2 \left( 1 - \frac{1 + \sigma^2}{2} \sqrt{1 - \beta} \right)^2 & \frac{7 - \sigma^2}{8} \leq \beta < 1, \quad 0 < \sigma^2 < 3, \\
0 & \frac{1}{2} < \beta < \frac{2 \sigma^2 - 1}{\sigma^2 + 1}, \quad \sigma^2 \geq 3, \\
2 \left( 1 - \frac{1 + \sigma^2}{2} \sqrt{1 - \beta} \right)^2 & \frac{2 \sigma^2 - 1}{\sigma^2 + 1} \leq \beta < 1, \quad \sigma^2 \geq 3.
\end{cases}
\]
(20)

Figure 2 depicts \( \rho_{\text{two-sample}}(\beta; \sigma) \) for several values of \( \sigma \).

### 2.3. Poisson Means

Consider the hypothesis testing problem
\[
\begin{align*}
H_0 \quad : \quad X_i & \overset{\text{iid}}{\sim} \text{Pois}(\lambda_i), \quad i = 1, \ldots, n, \\
H_1 \quad : \quad X_i & \overset{\text{iid}}{\sim} (1 - \epsilon)\text{Pois}(\lambda_i) + \epsilon\text{Pois}(\lambda'_i), \quad i = 1, \ldots, n,
\end{align*}
\]
where \( \lambda_1, \ldots, \lambda_n \) is a sequence of known means and for \( i = 1, \ldots, n, \lambda'_i \) obtained by perturbing \( \lambda_i \). For this model, we have the P-values
\[
p_i = \bar{P}(X_i; \lambda_i), \quad i = 1, \ldots, n,
\]
(22)
Unification of Rare/Weak Detection Models

$\beta$ (sparsity)

$\sigma^2 = 1/2$

$\sigma^2 = 1$

$\sigma^2 = 2$

Fig 2. Two-Sample Phase Diagram. The phase transition curve $\rho_{\text{two-sample}}(\beta; \sigma)$ of (20) defines the detection boundary for an asymptotically log-chisquared perturbation model (3). For $r < \rho_{\text{two-sample}}(\beta; \sigma)$, all tests are powerless. For $r > \rho_{\text{two-sample}}(\beta; \sigma)$, the Higher Criticism and the Berk-Jones tests are asymptotically powerful. The faint lines correspond to $2\rho(\beta; \sigma)$, where we have $\rho_{\text{two-sample}}(\beta; 1) = 2\rho(\beta; 1)$.

where $\bar{P}(x; \lambda_i) \equiv \Pr(x \geq \text{Pois}(\lambda_i))$. We suppose that the Poisson means increase with $n$ such that

$$(\min \lambda_i) / \log(n) \to \infty,$$  \hspace{1cm} (23)

and the perturbed means are given by

$$\lambda_i' = \lambda_i + \mu_n(r) \sqrt{\lambda_i}, \hspace{1cm} i = 1, \ldots, n.$$  \hspace{1cm} (24)

Noting that $\log(n)/\lambda_i' \to 0$ and $\lambda_i' - \lambda_i \to \infty$, the behavior of $p_i$ under $H_i^{(n)}$ is obtained using a moderate deviation estimate to the RV $Y_{\lambda_i'} \sim \text{Pois}(\lambda_i')$. This estimate leads to

$$-2 \log (\bar{P}(Y_{\lambda_i'}; \lambda_i)) \overset{D}{=} (Z + \mu_n(r))^2 (1 + o_p(1)), \hspace{1cm} Z \sim \mathcal{N}(0,1),$$  \hspace{1cm} (25)

which implies (7) with $\sigma = 1$ and $\mu = \mu_n$. It follows that a randomized version of the P-values $p_1, \ldots, p_n$ of (22) corresponds to a RMD model with log-chisquared parameters $(r, 1)$.

Arias-Castro and Wang studied the Poisson Means model (21) in [4]. They derived the optimal phase transition $\rho(\beta; 1)$, the Bonferroni phase transition $\rho_{\text{Bonf}}(\beta; 1)$, and showed that a version of HC is asymptotically powerful whenever $r > \rho(\beta; 1)$. 

where $\bar{P}(x; \lambda_i) \equiv \Pr(x \geq \text{Pois}(\lambda_i))$. We suppose that the Poisson means increase with $n$ such that

$$(\min \lambda_i) / \log(n) \to \infty,$$  \hspace{1cm} (23)

and the perturbed means are given by

$$\lambda_i' = \lambda_i + \mu_n(r) \sqrt{\lambda_i}, \hspace{1cm} i = 1, \ldots, n.$$  \hspace{1cm} (24)

Noting that $\log(n)/\lambda_i' \to 0$ and $\lambda_i' - \lambda_i \to \infty$, the behavior of $p_i$ under $H_i^{(n)}$ is obtained using a moderate deviation estimate to the RV $Y_{\lambda_i'} \sim \text{Pois}(\lambda_i')$. This estimate leads to

$$-2 \log (\bar{P}(Y_{\lambda_i'}; \lambda_i)) \overset{D}{=} (Z + \mu_n(r))^2 (1 + o_p(1)), \hspace{1cm} Z \sim \mathcal{N}(0,1),$$  \hspace{1cm} (25)

which implies (7) with $\sigma = 1$ and $\mu = \mu_n$. It follows that a randomized version of the P-values $p_1, \ldots, p_n$ of (22) corresponds to a RMD model with log-chisquared parameters $(r, 1)$.

Arias-Castro and Wang studied the Poisson Means model (21) in [4]. They derived the optimal phase transition $\rho(\beta; 1)$, the Bonferroni phase transition $\rho_{\text{Bonf}}(\beta; 1)$, and showed that a version of HC is asymptotically powerful whenever $r > \rho(\beta; 1)$.
2.4. Two-Sample Poisson Means

A two-sample version of (21) is given as:

\[ H_0^{(n)} : X_i, Y_i \overset{iid}{\sim} \text{Pois}(\lambda_i), \quad i = 1, \ldots, n. \]
\[ H_1^{(n)} : \begin{cases} X_i \overset{iid}{\sim} \text{Pois}(\lambda_i) \\ Y_i \overset{iid}{\sim} (1 - \epsilon)\text{Pois}(\lambda_i) + \epsilon\text{Pois}(\lambda'_i) \end{cases}, \quad i = 1, \ldots, n. \]  

(26)

Here \( \lambda_1, \ldots, \lambda_n \) is a sequence of unknown Poisson means that satisfy (23), while \( \lambda'_1, \ldots, \lambda'_n \) are defined as in (24). We summarize the significance of the pair \((X_i, Y_i)\) associated with the \(i\)-th feature by the RV:

\[ p_i \equiv \Phi\left(\frac{\sqrt{2Y_i} - \sqrt{2X_i}}{\sqrt{2}}\right), \]

for \( i = 1, \ldots, n \).

In order to analyze the behavior of \( p_1, \ldots, p_n \) under \( H_0^{(n)} \) and \( H_1^{(n)} \), note that the transformed Poisson RV \( \sqrt{X} \), \( X \sim \text{Pois}(... \right) \) is variance stable:

\[ 2\sqrt{X} - 2\sqrt{X_i} \to \mathcal{N}(0, 1). \]

It follows that under \( H_0^{(n)} \), \( \sqrt{2Y_i} - \sqrt{2X_i} \to \mathcal{N}(0, 1) \) hence \( p_i \overset{D}{\to} \text{Unif}(0, 1) \) as \( \lambda_i \to \infty \) implying that \( p_i \) are asymptomatic P-values. On the other hand, under \( H_1^{(n)} \), (23) and (24) imply

\[ \sqrt{\lambda'_i}(1 + o(1)) = \sqrt{\lambda_i} + \mu_n(r)/2, \]

where \( o(1) \to 0 \) as \( n \to \infty \) uniformly in \( i \). Consequently, with \( \tilde{Y}_i \sim \text{Pois}(\lambda'_i) \),

\[ \sqrt{2\tilde{Y}_i} - \sqrt{2X_i} = \sqrt{2\tilde{Y}_i} - \sqrt{2\lambda_i} - \left(\sqrt{2X_i} - \sqrt{2\lambda_i}\right) + \left(\sqrt{2\lambda'_i} - \sqrt{2\lambda_i}\right) \overset{D}{=} \left(Z + \mu_n(r)/\sqrt{2}\right)(1 + o_p(1)), \quad Z \sim \mathcal{N}(0, 1), \]

as \( n \to \infty \). By setting

\[ \tilde{p}_i \equiv \Phi\left(\sqrt{2\tilde{Y}_i} - \sqrt{2X_i}\right), \]

combining Mill’s ratio (15) and (28), we obtain

\[ -2\log(\tilde{p}_i) \overset{D}{=} \left(Z + \mu_n(r)/\sqrt{2}\right)^2(1 + o_p(1)). \]

(29)

The last evaluation shows that (8) holds with log-chisquared parameters \( (r/2, 1) \). It follows that the randomized version of \( p_1, \ldots, p_n \) correspond to a RMD model with these log-chisquared parameters.

For the model (26), Donoho and Kipnis [20] proposed to use P-values of exact binomial testing as in

\[ p'_i \equiv \Pr\left(\left|\text{Bin}(X_i + Y_i, 1/2) - \frac{X_i + Y_i}{2}\right| \leq \frac{|X_i - Y_i|}{2}\right), \quad i = 1, \ldots, n. \]  

(30)
which have several advantages over (27) in practice. Our RMD formulation shows that the optimal phase transition curves of both collections of P-values are identical and given by $\rho_{\text{two-sample}}(\beta; 1)$.

### 2.5. Two-sample $t$-Testing

Consider two populations and a set of $n$ independent features. Denote by $\nu_{*,i}$ the unknown mean of the $i$-th feature in population $*$, where $* \in \{x, y\}$ and $i \in \{1, \ldots, n\}$. Suppose that we have $n_{*,i}$ independent samples of feature $i$ from population $*$, and that we are interested in testing the global null

$$H_0 : \nu_{x,i} = \nu_{y,i} \quad \forall i = 1, \ldots, n.$$  \hfill (31)

This scenario arises in several high-dimensional learning tasks where the goal is to test whether two classes are distinguishable under certain transformations \[31]\; ; see also the recent works \[40, 38].

Given the data $\{X_{i,j}, Y_{i,k} : 1 \leq j \leq n_{x,i}, 1 \leq k \leq n_{y,i}\}$, we summarize the evidence provided by the $i$-th feature using a $t$-test against $H_{0,i} : \nu_{x,i} = \nu_{y,i}$. Specifically, with

$$\bar{X}_i = \frac{1}{n_{x,i}} \sum_{j=1}^{n_{x,i}} X_{i,j}, \quad \bar{Y}_i = \frac{1}{n_{y,i}} \sum_{k=1}^{n_{y,i}} Y_{i,k}$$

and

$$s_{x,i} = \frac{1}{n_{x,i} - 1} \sum_{j=1}^{n_{x,i}} (X_{i,j} - \bar{X}_i)^2, \quad s_{y,i} = \frac{1}{n_{y,i} - 1} \sum_{k=1}^{n_{y,i}} (Y_{i,k} - \bar{Y}_i)^2,$$  \hfill (32)

set

$$T_i = \frac{\bar{X}_i - \bar{Y}_i}{\sqrt{s_{x,i}^2/n_{x,i} + s_{y,i}^2/n_{y,i}}}.$$  \hfill (33)

Denote by $T_\kappa$ the $t$-distribution with $\kappa$ degrees of freedom. Under standard conditions ensuring asymptotic normality of $\bar{X}_i$, $\bar{Y}_i$, $s_{x,i}^2$, and $s_{y,i}^2,$

$$p_i = \Pr\{ |T_i| \geq |T_{n_{x,i}+n_{y,i}-2}| \}, \quad i = 1, \ldots, n,$$  \hfill (34)

are asymptotic P-values for (31). Similarly to the two-sample normal means model (17), we consider an alternative in which roughly $n\epsilon_n$ of the features’ mean obey $|\nu_{x,i} - \nu_{y,i}| = \mu_n$ while $\nu_{x,i} = \nu_{y,i}$ for the remaining ones. This situation can be written as

$$H_1^{(n)} : |\nu_{x,i} - \nu_{y,i}| = \begin{cases} \mu_n & i \in I \\
0 & i \notin I \end{cases}, \quad 1_{i \in I} \iid \text{Bernoulli}(\epsilon_n), \quad i = 1, \ldots, n.$$  \hfill (35)

The following proposition provides conditions under which the P-values of (34) conform to a RMD model with log-chisquared parameters $(r, 1)$. 

Proposition 2.1. For $i = 1, \ldots, n$, suppose that:

(i) The distributions of $X_{i,j}$ and $Y_{i,j}$ have densities.

(ii) $E[|X_{i,j}|^3] < \infty$ and $E[|Y_{i,j}|^3] < \infty$.

(iii) As $n \to \infty$, $n_{x,i} + n_{y,i} \to \infty$ while

$$\min_{i=1,\ldots,n} \frac{n_{x,i} + n_{y,i}}{(\log(n))^3} \to \infty.$$

(iv) There exists $c_{x,i}, c_{y,i} > 0$ such that $c_{x,i} \leq n_{x,i} / n_{y,i} \leq c_{y,i}$.

Suppose that $\mu = \mu_n(r)$. Under $H_1^{(n)}$,

$$-2 \log(p_i) \sim (1 - \epsilon)E_i^{(n)} + \epsilon Q_i^{(n)},$$

where $E_i^{(n)}$ and $Q_i^{(n)}$ are probability distributions obeying

$E_i^{(n)} \overset{D}{\to} \text{Exp}(2),$

and

$Q_i^{(n)} \overset{D}{=} (Z + \mu_n(r))^2 (1 + o_p(1)), \quad Z \sim \mathcal{N}(0, 1).$

We note that Delaigle, Hall, and Jin considered a high-dimensional version of the hypothesis testing problem defined by (31) and (35) in [15], for which they also derived a region where HC is asymptotically powerful.

3. Discussion

3.1. Log-Chisquared versus Log-Normal

It is interesting to compare our log-chisquared approximation for P-values under the alternative hypothesis to the classical log-normal approximation of Bahadur [6, 25] and Lambert and Hall [37]. Informally, suppose that the alternative hypothesis is characterized by a parameter $\theta$, and that $a_n$ is a sequence tending to infinity with $n$ describing the ‘cost’ of attaining new data. Bahadur’s log-normal approximation says that, under some conditions, a P-value $\pi$ under the alternative $H_1(\theta, a_n)$ obeys

$$\frac{\log(\pi) + a_n c(\theta)}{\sqrt{a_n}} \overset{D}{\to} \mathcal{N}(0, \tau^2(\theta)),$$  \hspace{1cm} (36)

as $n \to \infty$. It is convenient to write (36) as

$$\log(\pi) \overset{D}{=} \mathcal{N}(a_n c(\theta), a_n \tau^2(\theta)),$$  \hspace{1cm} (37)

In the terminology of [37], $c(\theta)$ is Bahadur’s half-slope describing the asymptotic behavior of the test’s size, i.e., the rate at which $\pi$ goes to zero. The asymptotic behavior of the test’s power is determined by both $\tau(\theta)$ and $c(\theta)$. 
It is well-recognized that (37) is a large deviation estimate of the test statistic in the following sense: if this statistic satisfies a large deviation principle, then $c(\theta)$ is a transformation of its rate function [49, 26, 50]. In contrast, in all RMD models of Section 2 the alternative hypotheses correspond to situations where the deviation of each test statistic from its null is on the moderate deviations scale in the sense of [47]. Consequently, the log-normal approximation of (37) is too rough to correctly indicate the asymptotic power of tests under RMD setting. To better illustrate this last point, consider the homoscedastic sparse normal means model (this is the model (13) with $\sigma = 1$)

$$H_0^{(n)} : X_i \overset{\text{iid}}{\sim} \mathcal{N}(0, 1),$$

$$H_1^{(n)} : X_i \overset{\text{iid}}{\sim} (1 - \epsilon)\mathcal{N}(0, 1) + \epsilon\mathcal{N}(\mu, 1),$$

with the P-values $p_i = \Phi(X_i)$. Under $H_1^{(n)}$, the distribution of $p_i$ is of the form

$$-2 \log p_i \sim (1 - \epsilon)\text{Exp}(2) + \epsilon Q_i^{(n)}, \quad (38)$$

where the probability $Q_i^{(n)}$ is the subject of our approximation. Suppose that $\mu$ and $\epsilon$ are calibrated to $n$ as in (5) and (4), respectively. In this paper we propose the log-chisquared approximation

$$Q_i^{(n)} \overset{D}{\sim} (\mu_n(r) + Z)^2. \quad (39)$$

On the other hand, we have

$$(\mu + Z)^2 = (\mu^2 + 2\mu Z)(1 + o_p(1)) = (\mu^2 + 2\mu Z)(1 + o_p(1)), \quad \mu \to \infty,$$

implying the log-normal approximation:

$$Q_i^{(n)} \overset{D}{\sim} \mathcal{N}(\mu_n^2(r), 4\mu_n^2(r)) = \mathcal{N}(2r \log(n), 8r \log(n)). \quad (40)$$

In particular, in the notation of (37) we have $\theta = r$, $a_n = \log(n)$, $c(\theta) = 2r$, and $\tau^2(\theta) = 8r$. Next, observe that the theoretical engine underlying the success of HC and the BJ tests is the behavior of

$$\Pr(\pi_i < n^{-q}), \quad \pi_i \sim Q_i^{(n)},$$

as $n \to \infty$. With $Q_i^{(n)}$ as in (39),

$$\Pr(\pi_i < n^{-q}) = \Pr(-2 \log(\pi_i) > 2q \log(n))$$

$$\sim \Pr\left( (\mu_n(r) + Z)^2 \geq 2q \log(n) \right) \quad (41)$$

$$\sim \Pr\left( Z \geq \sqrt{\log(n)}(\sqrt{2q} - \sqrt{2r}) \right).$$

A standard evaluation of the behavior of HC under $H_1^{(n)}$ uses (41) to show that it is asymptotically powerful for $r > \rho(\beta; 1)$ [12, 20]. On the other hand, with
\[ Q_i^{(n)} \] as in (40),
\[
\Pr(\pi_i < n^{-q}) = \Pr(\neg \log(\pi_i) > 2q \log(n)) \\
\sim \Pr(\mu_n(r)^2 + 2\mu_n(r)Z \geq 2q \log(n))
\]
\[ (42) \]
\[
= \Pr\left( Z \geq \sqrt{\log(n)} \frac{q-r}{\sqrt{2r}} \right)
\]
Since \[ \frac{q-r}{\sqrt{2r}} \geq \sqrt{2q} - \sqrt{2r}, \quad q \geq r > 0, \]
using the log-normal approximation in a formal exercise of would-be power analysis of HC by replacing (41) with (42), incorrectly predicts that HC is powerful for some \( r < \rho(\beta; 1) \).

### 3.2. Heteroscedasticity in RMD models

The phase transition described by \( \rho(\beta; \sigma) \) can be seen as the result of two distinct phenomena: (i) location shift controlled by \( r \), and (ii) heteroscedasticity controlled by \( \sigma^2 \). Roughly speaking, increasing the effect of either (i) or (ii) eases detection and reduces the phase transition curve, as seen in Figure 1. We refer to [11] for a comprehensive discussion on the effect of (ii) on the phase transition curve. In view of our results, the aforementioned discussion from [11] is relevant to any RMD model – not only to the rare/weak normal means model of [11] (see Section 2.1 above).

Comparing the effect of heteroscedasticity in one- versus two-sample settings, we see that
\[
\rho_{\text{two-sample}}(\beta; 1) = 2\rho(\beta; 1),
\]
an observation first made in [20]. Interestingly, as shown in Figure 2, this relation between \( \rho_{\text{two-sample}}(\beta; \sigma) \) and \( \rho(\beta; \sigma) \) does not hold when \( \sigma \neq 1 \). Specifically, detection in the two-sample homeostatic setting (\( \sigma = 1 \)) asymptotically requires twice the effect size. On the other hand, compared to the one-sample case, more than twice the effect size is needed for overdispersed mixtures (\( \sigma > 1 \)) and less for underdispersed ones (\( \sigma < 1 \)).

### 3.3. Other Generalizations of Rare/Weak Models

Cai and Wu [12] considered a rare/weak model in which all features obey the same sparse mixture under the alternative, while the distributions defining this mixture are quite general. In particular, the setting of [12] covers rare/weak feature models studied in [17, 1, 30, 33, 11, 12]. It does not cover, however, two-sample settings or cases where the features are not identically distributed as studied, for example, in [4, 20]. In view of these limitations, the approach we take here of modeling the P-values instead of the data is advantageous in RMD multiple testing situation as these P-values summarize evidence from identically or non-identically distributed tests in one- or two-samples.
Arias-Castro and Wang [5] provided another important generalization of rare/weak multiple testing settings when the null distribution is symmetric. For this case, they considered non-parametric HC- and Bonferroni-type tests and showed that these tests have interesting optimality properties. We anticipate that our RMD formulation applies to the setting of [5] when the non-symmetric behavior of an individual test statistic under the alternative hypothesis is at the moderate deviations scale. We leave the application of our formulation to the setting of [5] as future work.

4. Proofs

4.1. Technical Lemmas

Lemma 4.1. For \( q > r \), define

\[
\alpha(q; r, \sigma) \equiv \left( \frac{\sqrt{q} - \sqrt{r}}{\sigma} \right)^2.
\]

Suppose that \( Q_i^{(n)} \) satisfies (7). Then

\[
\lim_{n \to \infty} \frac{1}{\log(n)} \max_i \log \left( \frac{dQ_i^{(n)}}{d\text{Exp}(2)} (2q \log(n)) \right) = -\alpha(q; r, \sigma) + q, \quad q > r.
\]

Proof. For the density of \( \chi^2(r, \sigma) \), direct calculation implies

\[
\lim_{n \to \infty} \frac{1}{\log(n)} \log \left( \frac{d\chi^2(r, \sigma)}{d\text{Exp}(2)} (2q \log(n)) \right) = -\alpha(q; r, \sigma) + q, \quad q > r.
\]

From here, we see that (7) leads to (44). \( \square \)

We require the following lemma from [12], providing a particular version of Laplace’s principle.

Lemma 4.2. [12, Lemma 3] Let \((X, \mathcal{F}, \nu)\) be a measure space. Let \( F : X \times \mathbb{R}_+ \to \mathbb{R}_+ \) be measurable. Assume that

\[
\lim_{M \to \infty} \frac{\log F(x, M)}{M} = f(x)
\]

holds uniformly in \( x \in X \) for some measurable \( f : X \to \mathbb{R} \). If

\[
\int_X \exp(M_0 f(x))d\nu(x) < \infty
\]

for some \( M_0 > 0 \), then

\[
\lim_{M \to \infty} \frac{1}{M} \log \int_X F(x, M)d\nu(x) = \text{ess sup}_{x \in X} f(x).
\]
Lemma 4.3. Suppose that $-2\log(X_i) \sim Q_i^{(n)}$, $i = 1, \ldots, n$ where $Q_i^{(n)}$ satisfy (7). For $q > r$,

$$
\lim_{n \to \infty} \frac{1}{\log(n)} \Pr(X_i \leq n^{-q}) = -\alpha(q; r, \sigma).
$$

(48)

Proof.

$$
\Pr[X_i \leq n^{-q}] = \Pr[-2\log(X_i) > 2q \log(n)] = \int_{2q \log(n)}^\infty dQ_i^{(n)}
$$

(49)

$$
= 2 \log(n) \int_{q}^{\infty} \frac{Q_i^{(n)}}{\chi^2_2}(2 \log(n)y)^2(2 \log(n)dy)
$$

$$
= \int_{q}^{\infty} n^{-\alpha(y; r, \sigma) + o(1)} dy,
$$

(50)

where in the last transition we used (7), $\text{Exp}(2)(du) = \frac{1}{2} e^{-u/2} du$, and $\log(n) n^{o(1)} = n^{o(1)}$. We now apply Lemma 4.2 to (50) with $X = [q, \infty)$, $M = \log(n)$, $F(x, M) = n^{-\alpha(x; r, \sigma) + o(1)}$, $f(x) = -\alpha(x; r, \sigma)$, and $\nu$ the Lebesgue measure. Note that (46) holds because

$$
\int_{q}^{\infty} e^{-\log(n)\alpha(x; r, \sigma)} dx = \int_{q}^{\infty} e^{-\log(n)(\frac{\sqrt{x} - \sqrt{r}}{\sigma})^2} dx < \infty.
$$

We obtain:

$$
\lim_{n \to \infty} \frac{1}{\log(n)} \log(\Pr[X_i \leq n^{-q}]) = \sup_{x \in [q, \infty)} (-\alpha(y; r, \sigma)) = -\alpha(q; r, \sigma),
$$

(51)

where in the last transition we used that $q > r$. 

4.2. Proof of Theorem 1.1

The proof closely follow the proofs of Theorem 1 of [12].

Recall that the total variation and the Hellinger distances of two probability measures $P$ and $Q$ are defined as

$$
\text{TV}(P, Q) := \sup_{A} |P(A) - Q(A)|,
$$

(52)

and

$$
\text{H}^2(P, Q) := \frac{1}{2} \int \left(\sqrt{dP} - \sqrt{dQ}\right)^2,
$$

(53)

respectively. The two measures are related by the inequalities

$$
\text{H}^2(P, Q) \leq \text{TV}(P, Q) \leq \sqrt{2} \text{H}(P, Q).
$$

(54)
Also recall that for product measures \( P = \prod_{i=1}^{n} P_i, Q = \prod_{i=1}^{n} Q_i \) we have
\[
H^2(P, Q) = 2 - 2 \sum_{i=1}^{n} \left( 1 - \frac{H^2(P_i, Q_i)}{2} \right)^2.
\] (55)

Denote
\[
H_{0,i} : -2 \log(p_i) \sim \text{Exp}(2)
\] (56)
\[
H_{1,i}^{(n)} : -2 \log(p_i) \sim (1 - \epsilon_n)\text{Exp}(2) + \epsilon_n Q_i^{(n)}
\] (57)
\[
\bar{H}_{1,i}^{(n)} : -2 \log(p_i) \sim (1 - \epsilon_n)\text{Exp}(2) + \epsilon_n \chi^2_r(\sigma).
\] (58)

For the hypothesis testing problem (3), a standard argument says that all tests are asymptotically powerless whenever
\[
\text{TV}(H_0, H_1^{(n)}) = o(1).
\] (59)

From (54), it follows that (59) holds whenever the Hellinger distance between \( H_0 \) and \( H_1^{(0)} \) vanishes as \( n \to \infty \), while (55) implies that this is the case whenever
\[
H^2(H_{0,i}, H_{1,i}^{(n)}) = o(1/n),
\] (60)
uniformly in \( i \). To summarize, it is enough to show that (60) holds whenever \( r < \rho(\beta; \sigma) \).

Below, the expectation is with respect to \( X \sim \text{Exp}(2) \).

\[
2H^2(H_{0,i}^{(n)}, H_{1,i}^{(n)}) = \int \left( \sqrt{dH_{1,i}^{(n)}} - \sqrt{dH_{0,i}^{(n)}} \right)^2
\] (61)
\[
= \int \left( \frac{dH_{1,i}^{(n)}}{dH_{0,i}^{(n)}} - 1 \right)^2 dH_{0,i}^{(n)}
\] (62)
\[
= \mathbb{E} \left[ \left( \frac{dH_{1,i}^{(n)}}{d\text{Exp}(2)(X)} - 1 \right)^2 \right]
\] (63)
\[
= \mathbb{E} \left[ \left( \frac{1}{1 + \epsilon_n (e^{\epsilon_n(X)} - 1)} - 1 \right)^2 \right].
\] (64)

Using that \((\sqrt{1-t} - 1)^2 < t^2\), for \( 0 < t < 1 \),
\[
\mathbb{E} \left[ \left( \frac{1}{1 + \epsilon_n (e^{\epsilon_n(X)} - 1)} - 1 \right)^2 \mathbbm{1}_{e_n(X) < 0} \right]
\] (65)
\[
\leq (\sqrt{1 - \epsilon_n} - 1)^2 \leq \epsilon_n^2 = n^{-2\beta} = o(n^{-1}).
\] (66)
It is left to consider the case \( \ell_{n,i}(X) \geq 0 \). Set \( Y = X/(2 \log(n)) \). We have:

\[
E \left[ \left( \sqrt{1 + \epsilon_n \left( e^{f_{X,Y}} - 1 \right)} - 1 \right)^2 1_{\ell(X) \geq 0} \right] \\
= E \left[ \left( \sqrt{1 + \epsilon_n \left( e^{f_{X,Y}(2 \log(n))} - 1 \right)} - 1 \right)^2 1_{\ell_{n,i}(X) \geq 0} \right] \\
\leq E \left[ \left( \sqrt{1 + \epsilon_n \left( n^{Y_o(Y,r,s) + o(1)} - 1 \right)} - 1 \right)^2 \right] \\
\leq E \left[ \epsilon_n n^{Y_o(Y,r,s) + o(1)} \land \epsilon_n n^{2Y - 2\alpha(Y,r,s) + o(1)} \right] \\
= E \left[ n^{(Y_o(Y,r,s)) \lor (2Y - 2\beta - 2\alpha(Y,r,s) + o(1))} \right] \\
= \log(n) \int_0^\infty n^{(-\beta - \alpha(y,r,s)) \lor (-2\beta - 2\alpha(y,r,s) + y) + o(1)} dy, \\
= \log(n) \int_0^\infty e^{(-\beta - \alpha(y,r,s)) \lor (-2\beta - 2\alpha(y,r,s) + y) + o(1)) \log(n)} dy,
\]

where (67) is due to Lemma 4.1, (68) is due to the inequality

\[
(\sqrt{1 + t^2} - 1)^2 \leq t^2, \quad t > 0,
\]

and (69) follows since \( Y \log(n) \) has an exponential distribution. As \( r < \rho(\beta; \sigma) \), there exists \( \delta > 0 \) such that

\[
\max_{0 < q \leq 1} \left( \frac{1 + q}{2} - \alpha(q; r, \sigma) \right) + \delta - \beta = 0.
\]

We now apply Lemma 4.2 to (70) with \( X = [0, \infty) \), \( M = \log(n) \),

\[
f(x) = (-\beta - \alpha(x; r, \sigma)) \land (-2\beta - 2\alpha(x; r, \sigma) + x),
\]

and \( F(x, M) = e^{M(f(x) + o(1))} \). Note that (46) is satisfied since

\[
\int_0^\infty e^{\log(n)(-\beta - \alpha(y,r,s)) \lor (-2\beta - 2\alpha(y,r,s) + y)} dy \leq \int_0^\infty n^{-\beta - \alpha(y,r,s)} dy \\
= n^{-\beta} \int_0^\infty \exp \left\{ -\log(n) \left( \frac{\sqrt{y} - \sqrt{1}}{\sigma} \right)^2 \right\} dy < \infty.
\]

We conclude

\[
E \left[ \left( \sqrt{1 + \epsilon_n \left( e^{f_{X,Y}} - 1 \right)} - 1 \right)^2 1_{\ell(Y) \geq 0} \right] \\
= n^{\sup_y (-\beta - \alpha(x; r, \sigma)) \lor (-2\beta - 2\alpha(x; r, \sigma) + x) + o(1)} \\
\leq n^{-1 - \delta + o(1)} = o(1/n),
\]
where the last transition follows because (72) implies
\[
\sup_x (-\beta - \alpha(x; r, \sigma)) \lor (-2\beta - 2\alpha(x; r, \sigma) + x) \leq -1 - \delta.
\]
Putting everything together, we obtain
\[
H^2 \left( H^{(n)}_{0, i}, H^{(n)}_{1, i} \right) = o(1/n), \quad (73)
\]
and the proof is completed. \(\square\)

4.3. Proof of Theorem 1.2

The proof requires the following Lemma from [20].

**Lemma 4.4.** [20, Lem. 5.7] Let \( F_n(t) \) be the normalized sum of \( n \) independent random variables. Fix \( q \in (0, 1) \) and \( \beta > 0 \). Suppose that
\[
\mathbb{E} \left[ F_n(n^{-q}) \right] = n^{-q+o(1)} \left( 1 - n^{-\beta} \right) + n^{-\beta} n^{-q+o(1)}, \quad (74)
\]
for two real-valued and non-negative functions \( \delta(\cdot) \) and \( \gamma(\cdot) \) with \( \delta(q) < q \) and
\[
\delta(q) + \beta < \gamma(q). \quad (75)
\]
For a positive sequence \( \{a_n\}_{n=1}^\infty \) obeying \( a_n n^{-\eta} \to 0 \) for any \( \eta > 0 \), we have
\[
\Pr(n^{\gamma(q)} (F_n(n^{-q}) - n^{-q}) \leq a_n) \to 0, \quad n \to \infty.
\]

It follows from [17, Thm. 1.1] that
\[
\Pr_{H_0^*} \left[ H_{C_n}^* \leq \sqrt{4 \log \log(n)} \right] \to 0. \quad (76)
\]
Therefore, it is enough to show that
\[
\Pr_{H_1^*} \left[ H_{C_n} \geq \log(n) \right] \to 0. \quad (77)
\]

Set
\[
F_n(t) \equiv \frac{1}{n} \sum_{i=1}^{n} 1_{p_i \leq t}.
\]
As
\[
H_{C_n}^* = \sup_{1/n \leq u \leq 1} \sqrt{n} \frac{F_n(u) - u}{\sqrt{u(1-u)}} \quad (78)
\]
almost surely, for \( t > 1/n \) we have:
\[
H_{C_n}^* \geq \sqrt{n} \frac{F_n(t) - t}{\sqrt{t(1-t)}}. \quad (79)
\]
Therefore, setting \( t_n = n^{-q} \) for \( q \leq 1 \), we obtain:

\[
\Pr_{H_1^{(n)}}[\text{HC}_n^* \leq \log(n)] \leq \Pr_{H_1^{(n)}}\left(\sqrt{n} \frac{F_n(t_n) - t_n}{\sqrt{t_n(1 - t_n)}} \leq \log(n)\right)
\]

\[
\leq \Pr_{H_1^{(n)}}\left[n^{q+1} (F_n(t_n) - t_n) \leq \log(n)\right].
\] (80)

Apply Lemma 4.4 to (80) with \( \delta(q) = \alpha(q; r, \sigma) \), \( \gamma(q) = (q + 1)/2 \), and \( a_n = \log(n) \) to conclude that (80) goes to zero as \( n \to \infty \). Theorem 1.2 follows.

4.4. Proof of Theorem 1.4

For the test \( p_{(1)} = \min_{i=1, \ldots, n} p_i \), we show that whenever \( r > \rho_{\text{Bonf}}(\beta; \sigma) \), along the sequence of thresholds \( a_n = 1/(n \log(n)) \) for \( n = 1, 2, \ldots \), we have \( \Pr_{H_0}(p_{(1)} > a_n) \to 1 \) while \( \Pr_{H_1^{(n)}}(p_{(1)} > a_n) \to 0 \).

Indeed,

\[
\Pr_{H_0}[p_{(1)} \leq a_n] = 1 - \prod_{i=1}^n (p_i > a_n)
\]

\[
= 1 - (1 - a_n)^n \to 0.
\] (81)

On the other hand,

\[
\Pr_{H_1^{(n)}}[p_{(1)} > a_n] = \prod_{i=1}^n \Pr_{H_1^{(n)}}[p_i > a_n]
\]

\[
= \prod_{i=1}^n \left(1 - \Pr_{H_1^{(n)}}[p_i \leq a_n]\right),
\] (82)

hence it is enough to show that \( \Pr_{H_1^{(n)}}[p_i \leq a_n] = o(1/n) \) uniformly in \( i \). Let

\[
\eta \equiv 1 - \alpha(1; r, \sigma) - \beta.
\] (83)

The condition \( r > \rho_{\text{Bonf}}(\beta; \sigma) \) implies \( \eta > 0 \). By continuity of \( \alpha(1; r, \sigma) \) in \( r \), there exits \( \delta > 0 \) such that

\[
\alpha(1 - \delta; r, \sigma) + \beta < 1 + \eta/2.
\] (84)

Let \( X_i \) be a RV with law \( -2 \log(X_i) \overset{D}{=} Q_i^{(n)} \), for \( i = 1, \ldots, n \). We have:

\[
\Pr_{H_1^{(n)}}[p_i \leq a_n] = (1 - \epsilon_n)a_n + \epsilon_n \Pr[X_i \leq a_n]
\]

\[
\geq \epsilon_n \Pr[X_i \leq a_n]
\]

\[
\geq \epsilon_n \Pr[X_i \leq n^{-(1-\delta)}]
\]

\[
= n^{-\beta-\alpha(1-\delta; r, \sigma)(1+o(1))}
\]

\[
\geq n^{-(1+\eta/2)(1+o(1))},
\] (85) (86) (87)
where \( (85) \) holds for all \( n \geq n_0(\delta) \) large enough, \( (86) \) follows from Lemma 4.3, and \( (87) \) follows from \( (84) \).

### 4.5. Proof of Theorem 1.3

The proof is similar to the proof of [42, Thm. 4.4]. In particular we use:

**Lemma 4.5.** [42, Cor. A1] Let \( \{\alpha_n\}_{n=1}^{\infty} \) be a sequence converging to infinity. Let \( \mu_n, \sigma_n^2, \) and \( f_n \) denote the mean, variance and density of \( \text{Beta}(\alpha_n, n - \alpha_n + 1) \), respectively. Let \( g(n) \) be any positive function satisfying \( g(n) = o(\min\{\alpha_n, n - \alpha_n\}) \) as \( n \to \infty \). Then,

\[
f_n(\mu_n + \sigma_n \cdot t) \geq \frac{e^{-t^2/2}}{\sqrt{2\pi \cdot \sigma_n}} \left( 1 - \frac{t^3}{\sqrt{g(n)}} - \frac{1}{g(n)} \right)
\]

Recall that \( M_n^- = \min_{i=1,\ldots,n} \pi_i \), where

\[
\pi_i = \Pr[\text{Beta}(i, n - i + 1) \leq p(i)], \quad i = 1, \ldots, n.
\]

The limiting distribution of \( M_n \) under \( H_0 \) is provided in [27] and [42, Thm 4.1], from which it easily follows that

\[
\Pr_{H_0}[M_n^- \leq n^{-1}] \to 0.
\]

For \( X \sim \text{Beta}(i, n - i + 1) \), set

\[
\mu_i = \mathbb{E}[X] = \frac{i}{n + 1}, \quad \sigma_i^2 = \text{Var}[X] = \frac{i(n - 1 + 1)}{(n + 1)^2(n + 2)},
\]

hence, for \( x \in \mathbb{R} \),

\[
\frac{\mu_i - x}{\sigma_i} = \sqrt{n} \frac{i/n - x}{\sqrt{\frac{i}{n} \left(1 - \frac{i}{n}\right)}} (1 + o(1)). \tag{90}
\]

The proof of Theorem 1.2 in Section 4.3 shows that

\[
\Pr_{H_1^{(n)}} \left[ \max_i \sqrt{n} \frac{i/n - p(i)}{\sqrt{\frac{i}{n} \left(1 - \frac{i}{n}\right)}} \geq \log(n) \right] \to 1. \tag{91}
\]

Together with \( (90) \), the last display implies that for any \( \delta > 0 \) there exists \( n_0(\delta) \) and \( i^* \in \{1, \ldots, n\} \) such that

\[
\tau^* \equiv \frac{\mu_{i^*} - p(i^*)}{\sigma_{i^*}} \geq \sqrt{2\log(n)}, \tag{92}
\]
with probability at least $1 - \delta$. Denote by $f_i$ the density $f_i : [0, 1] \to \mathbb{R}^+$ of Beta$(i, n - i + 1)$. We have
\[
\pi_{i^*} = \int_0^{P(i^*)} f_i^*(x)dx \\
= \sigma_{i^*} \int_{-\mu_{i^*}/\sigma_{i^*}}^{\tau_{i^*}} f_i^*(\mu_{i^*} + \sigma_{i^*}t)dt \\
\leq \sigma_{i^*} \int_{-\infty}^{\tau_{i^*}} f_i^*(\mu_{i^*} + \sigma_{i^*}t)dt \\
\leq \int_{\tau_{i^*}}^{\infty} \frac{1 + o(1)}{\sqrt{2\pi}} e^{-x^2/2}dx \\
= (1 - \Phi(\tau^*))((1 + o(1)) \sim \frac{1}{\tau^*} e^{-\tau^*/2},
\]
where (93) follows from Lemma 4.5 and (94) is due to Mills’ ratio. Consequently,
\[
\pi_{i^*} \leq n^{-1}, \quad \text{for} \quad n \geq n_0(\delta),
\]
with probability at least $1 - \delta$. Hence
\[
[M_n \leq n^{-1}] \geq \Pr[M_n^r \leq n^{-1}] \geq \Pr[\pi_{i^*} \leq n^{-1}] \geq 1 - \delta,
\]
for $n \geq n_0(\delta)$. Together with (89), the last display implies that the sequence of thresholds $t_n = 1/n$ perfectly separates $H_0$ from $H_1^{(n)}$.

4.6. Proof of Theorem 1.5

The proof is similar to the proof of Theorem 1.4 in [17]. The main idea is to establish the following claims:

(i) Inference based on FDR thresholding ignores P-values in the range $(n^{-\delta}, 1]$, for $\delta < 1$.

(ii) When $r < p_{\text{Bonf}}(\beta; \sigma)$, P-values smaller than $n^{-\delta}$ under $H_1^{(n)}$ are as frequent as under $H_0^{(n)}$.

In order to establish (i) and (ii), define, for an interval $I \subset (0, 1)$,
\[
T_I = \min_{i : P(i) \in I} \frac{P(i)}{i/n}.
\]

\[
\]
For some $\delta > 0$ and a sequence $\{a_n\}_{n=1}^{\infty}$ of threshold values with $\lim \inf a_n = 0$,

$$\left| \Pr_{H_0} [\text{FDR rejects}] - \Pr_{H_1^{(n)}} [\text{FDR rejects}] \right|$$

$$= \left| \Pr_{H_0} [T_{[0,1]} < a_n] - \Pr_{H_1^{(n)}} [T_{[0,1]} < a_n] \right|$$

$$+ \Pr_{H_1^{(n)}} [T_{(n-\delta,1]} < a_n] + \Pr_{H_0} [T_{(n-\delta,1]} < a_n]$$

$$\leq \left| \Pr_{H_1^{(n)}} [T_{(0,n-\delta]} < a_n] - \Pr_{H_0} [T_{(0,n-\delta]} < a_n] \right|.$$  \hfill (98)

Note that the terms in (98) are associated with (i) while (99) is associated with (ii).

The following lemma implies that the terms in (98) vanish as $n \to \infty$.

**Lemma 4.6.** Assume that $r < \rho_{\text{Bonf}}(\beta; \sigma)$. For any $0 < a < 1$ and $\delta < 1$,

$$\Pr_{H_1^{(n)}} [T_{(n-\delta,1]} < a] \to 0.$$  \hfill (101)

The proof of Lemma 4.6 is in Section 4.7 below. We now focus on the term (99). Let $I \subset \{1, \ldots, n\}$ be a random set such that $i \in I$ with probability $\epsilon_n = n^{-\beta}$. An equivalent way of specifying $H_1^{(n)}$ is

$$-2 \log(p_i) \sim \begin{cases} Q_i^{(n)} & i \in I \\ \text{Exp}(2) & i \notin I. \end{cases}$$  \hfill (102)

Let $X_i$ be a RV with $-2 \log(X_i) \overset{D}{=} Q_i^{(n)}$, $i = 1, \ldots, n$. Choose $\delta > 0$ such that

$$\alpha(r; \sigma) + \beta + \delta < 1,$$  \hfill (103)

which is possible, since $r < \rho(\beta; \sigma)$. Consider the event:

$$E_n^\delta \equiv \{p_i \leq n^{-\delta} \text{ for some } i \in I\}.$$  

Conditioned on the event $|I| = M$, we have

$$\Pr [E_n^\delta \mid |I| = M] = \Pr \left[ \min_{i=1,\ldots,n} X_i \leq n^{-\delta} \mid |I| = M \right]$$

$$\leq 1 - \left( 1 - n^{-\alpha(\delta; \sigma)(1+o(1))} \right)^M$$  \hfill (104)

$$\leq M \cdot n^{-\alpha(\delta; \sigma)(1+o(1))}.$$

\hfill (105)
where (104) follows from Lemma 4.3 and (105) follows from the inequality $M \cdot \log(1 + x) > \log(1 + Mx)$, $x \geq -1$. As $M \sim \text{Bin}(n, \epsilon_n)$, hence $\Pr[M > n^{1+\delta/2}\epsilon_n] \to 1$. Consequently, for any $\epsilon$,
\[
\Pr(M \cdot n^{-\alpha(\delta;r,\sigma)(1+o(1))} > \epsilon) \leq o(1) + \Pr(n^{1-\beta-\delta/2-\alpha(\delta;r,\sigma)(1+o(1))} > \epsilon) \to 0,
\]
and hence $\Pr[E_n^d] \to 0$. From here, since
\[
\Pr_{H_i^{(n)}}[T_{[0,n^{-\delta}]} < a_n \mid (E_n^d)^c] = \Pr_{H_0}[T_{[0,n^{-\delta}]} < a_n],
\]
we get
\[
\Pr_{H_i^{(n)}}[T_{[0,n^{-\delta}]} < a_n] = \Pr_{H_i^{(n)}}[(E_n^d)^c] \cdot \Pr_{H_i^{(n)}}[T_{[0,n^{-\delta}]} < a_n \mid (E_n^d)^c]
+ \Pr_{H_i^{(n)}}[E_n^d] \cdot \Pr_{H_i^{(n)}}[T_{[0,n^{-\delta}]} < a_n \mid E_n^d]
= \Pr_{H_i^{(n)}}[T_{[0,n^{-\delta}]} < a_n \mid (E_n^d)^c] + o(1)
= \Pr_{H_0}[T_{[0,n^{-\delta}]} < a_n] + o(1).
\]
This complete the proof. \hfill \Box

4.7. Proof of Lemma 4.6

Let $F_n(t) \equiv n^{-1} \sum_{i=1}^n 1_{p_i \leq t}$ be the empirical CDF of $p_1, \ldots , p_n$. Note that $i/n = F_n(p_{(i)})$, hence
\[
\frac{p_{(i)}}{i/n} \leq a \iff F_n(p_{(i)}) \geq p_{(i)}/a.
\]
Consequently,
\[
\Pr_{H_i^{(n)}}[T_{[n^{-\alpha},1]} \leq a] \leq \sup_{t > n^{-\delta} H_i^{(n)}} \Pr_{H_i^{(n)}}[F_n(t) \geq t/a]
= \sup_{t > n^{-\delta} H_i^{(n)}} \Pr_{H_i^{(n)}}[nF_n(t) \geq nt/a]
= \sup_{t > n^{-\delta} H_i^{(n)}} \Pr_{H_i^{(n)}}[nF_n(t) \geq \mathbb{E}_{H_i^{(n)}}[nF_n(t)](1 + \kappa)],
\]
where
\[
\kappa \equiv \kappa(n, a, t) \equiv \frac{t}{a\mathbb{E}[F_n(t)]} - 1.
\]
Let \( U_i \sim \text{Unif}(0, 1) \) and \(-2 \log(X_i) \sim Q_{i}^{(n)} \), for \( i = 1, \ldots, n \). Using the parametrization \( t_n = n^{-\delta} \), \( q \leq \delta < 1 \),

\[
E_{H_{i}^{(n)}}[F_{n}(t_{n})] = \frac{1}{n} \sum_{i=1}^{n} \Pr_{H_{i}^{(n)}}[p_{i} \leq n^{-q}]
\]

(109)

\[
= (1 - \epsilon_{n}) [U_{i} \leq n^{-q}] + \epsilon_{n} \Pr[X_{i} \leq n^{-q}]
\]

(110)

\[
= 1 - \epsilon_{n} + n^{-\alpha(q; r, \sigma)(1 + o(1)) - \beta},
\]

(111)

where the last transition follows from Lemma 4.3. Since \( \beta + \alpha(q; r, \sigma) \leq \beta + \alpha(1; r, \sigma) < 1 \), the last display implies \( E_{H_{i}^{(n)}}[F_{n}(t_{n})]/t_{n} \rightarrow 1 \). It follows that

\[
\sup_{t > n^{-\delta}} \frac{E_{H_{i}^{(n)}}[F_{n}(t_{n})]}{t} = 1 + o(1).
\]

(112)

Since \( a < 1 \), there exists \( \eta > 0 \) such that \( \kappa \geq 1/a - 1 + \eta > 0 \) for all \( n \geq n_{0}(\delta) \) large enough. Using Chernoff’s inequality \([41, \text{Ch. 4}]\) in (107), we obtain

\[
\Pr_{H_{i}^{(n)}}[T_{[n^{-\delta}, 1]} \leq a] \leq \sup_{t > n^{-\delta}} \exp \left\{ -\frac{n}{2a} \frac{\kappa^{2}}{1 + \kappa} E_{H_{i}^{(n)}}[F_{n}(t)] \right\}
\]

\[
\leq \exp \left\{ -\frac{n}{2a} \inf_{t > n^{-\delta}} E_{H_{i}^{(n)}}[F_{n}(t)] \right\}
\]

\[
= \exp \left\{ -\frac{1}{2a} n^{1-\alpha(\delta; r, \sigma)(1 + o(1)) - \beta} \right\} \rightarrow 0,
\]

where the last transition follows because \( r < \rho^{\text{Bonf}}(\beta; \sigma) \) implies \( \beta + \alpha(\delta; r, \sigma) \leq \beta + \alpha(1; r, \sigma) < 1 \). \( \square \)

### 4.8. Proof of Theorem 1.6

Since \( F_{n} \sim \chi^{2}_{2n} \) under \( H_{0} \), we have

\[
E[F_{n}|H_{0}] = 2n, \quad \text{Var}[F_{n}|H_{0}] = 4n.
\]

(113)

As \( F_{n} \) is asymptotically normal, it is enough to show that

\[
E\left[F_{n}|H_{i}^{(n)}\right] \sim 2n, \quad \text{and} \quad \text{Var}\left[F_{n}|H_{i}^{(n)}\right] \sim 4n.
\]

(114)

Note first that for the special case \( X \sim \chi^{2}(r, \sigma) \), we have

\[
E[X] = \mu_{n}(r)^{2} + \sigma^{2}, \quad E[X^{2}] = \mu_{n}(r)^{4} + 4\mu_{n}^{2}\sigma^{2} + 3\sigma^{4}.
\]

(115)

It follows that with \( Q_{i}^{(n)} = \chi^{2}(r, \sigma) \),

\[
E\left[F_{n}|H_{i}^{(n)}\right] = 2n(1 - \epsilon_{n}) + \epsilon_{n}\text{Poly}(\sqrt{\log(n)}) = 2n + o(1),
\]

\[
E\left[F_{n}|H_{i}^{(n)}\right] = 2n(1 - \epsilon_{n}) + \epsilon_{n}\text{Poly}(\sqrt{\log(n)}) = 2n + o(1),
\]
where \( \text{Poly}(t) \) indicates some polynomial in \( t \). Similarly, we have \( \mathbb{E} \left[ F^2_n | H^{(n)}_1 \right] = 4n + o(1) \), hence (114) holds in this case. For the general case \( X \sim Q_i^{(n)} \), we use the RMD condition (7) and that \( Q_i^{(n)} \) is stochastically smaller than Unif(0, 1) to deduce an equivalence between the moments of \( Q_i^{(n)} \) and \( \chi^2(r, \sigma) \) up to \( n^{o(1)} \) terms.

### 4.9. Proof of Proposition 2.1

The proof requires the characterization of the \( t \)-statistic under moderate deviations in the form provided in [13]:

**Lemma 4.7.** [13, Theorem 1.2] In the notation of Section 2.5, set \( X(j) = X_{1,j}, Y(j) = Y_{1,j}, \bar{X} = \bar{X}_1, \bar{Y} = \bar{Y}_1, \nu_x = \nu_{x,1}, \nu_y = \nu_{y,1}, s_1 = s_{x,1}, s_2 = s_{y,1}, n_x = n_{x,1}, n_y = n_{y,1}, n = n_x + n_y \), and

\[
T_n = \frac{\bar{X} - \bar{Y} - (\nu_x - \nu_y)}{\sqrt{\frac{s^2_x}{n_x} + \frac{s^2_y}{n_y}}},
\]

(116)

Assume \( \mathbb{E} \left[ |X(1)|^3 \right] < \infty \mathbb{E} \left[ |Y(1)|^3 \right] < \infty \) and that there are \( 0 < c_x \leq c_y < \infty \) such that \( c_x \leq n_x/n_y \leq 1 \). Then

\[
\frac{\mathbb{P}(T_n \geq u)}{\Phi(u)} \to 1
\]

(117)

uniformly in \( u \in (0, o(n^{1/6})) \).

Lemma 4.7 says that for deviations smaller than \( n^{1/6} \), the \( t \)-statistic (116) behaves asymptotically like a standard normal RV. In particular, under \( H^{(n)}_0 \), this lemma implies that \( p_i \) converges in distribution to Unif(0, 1). We now consider the distribution of \( p_i \) under \( H^{(n)}_1 \). Denote \( t(x; n) \equiv \mathbb{P}(|x| \geq |T_n|) \) and \( z(x) \equiv \mathbb{P}(|x| \geq |N(0, 1)|) \). The standard convergence of the \( t \)-distribution to the normal distribution implies

\[
\sup_{q>0} \left| t(\sqrt{q \log(n)}; n) - z(\sqrt{q \log(n)}) \right| = o(n^{-1}).
\]

(118)
Therefore, if $p_i$ is associated with the case $\nu_x \neq \nu_y$, for $q > r$ we get

$$\Pr[-2\log(p_i) \geq -2q\log(n)] = \Pr[\Pr[|T_i| > |T_{n-2}|] \leq n^{-q}]$$
$$= \Pr[\Phi(|T_i|; n-2) \leq n^{-q}]$$
$$= \Pr[\Phi(|T_i| + o(n^{-1}) \leq n^{-q}]$$
$$= \Pr[|T_i| > \sqrt{2q\log(n)} + o(1)]$$

(119)

$$= \Phi\left(\sqrt{2q\log(n)} - |\nu_{x,i} - \nu_{y,i}|\right) (1 + o(1))$$

(120)

$$= \Phi\left(\sqrt{2q\log(n)} - \sqrt{2r\log(n)}\right) (1 + o(1))$$

(121)

$$= n^{-\sqrt{q-r}\tau^2} (1 + o(1)) = n^{-\alpha(q,r,1)} (1 + o(1))$$

(122)

where (119) follows from (118), (120) is due to properties of the quantile function of the normal distribution as implied by Mills’ ratio, (121) follows from Lemma 4.7 as Condition (iii) implies $\sqrt{2q\log(n)} = o(n^{1/6})$ for $q > 0$, and (122) follows from Mills’ ratio.

From Lemma 4.3, we see that the tail of $p_i$ is asymptotically identical to the tail of $\chi^2(r,1)$. Therefore condition (7) holds due to the assumption that $X^{(j)}$ and $Y^{(j)}$ have densities. \hfill \square
