ABSTRACT

We consider the fixed-budget best arm identification problem in the multi-armed bandit problem. One of the main interests in this field is to derive a tight lower bound on the probability of misidentifying the best arm and to develop a strategy whose performance guarantee matches the lower bound. However, it has long been an open problem when the optimal allocation ratio of arm draws is unknown. In this paper, we provide an answer for this problem under which the gap between the expected rewards is small. First, we derive a tight problem-dependent lower bound, which characterizes the optimal allocation ratio that depends on the gap of the expected rewards and the Fisher information of the bandit model. Then, we propose the “RS-AIPW” strategy, which consists of the randomized sampling (RS) rule using the estimated optimal allocation ratio and the recommendation rule using the augmented inverse probability weighting (AIPW) estimator. Our proposed strategy is optimal in the sense that the performance guarantee achieves the derived lower bound under a small gap. In the course of the analysis, we present a novel large deviation bound for martingales.

1 Introduction

We study the best arm identification (BAI) with a fixed budget in stochastic multi-armed bandit (MAB) problems. The goal is to identify an arm that has the highest expected reward with the smallest failure probability under a fixed number of rounds, called a budget. (Bubeck et al., 2009; Audibert et al., 2010; Kaufmann et al., 2016; Carpentier and Locatelli, 2016). Formally, we consider the following bandit process given a fixed budget $T$: an agent selects an arm $A_t \in [K] = \{1, 2, \ldots, K\}$ at time $t \in [T] = \{1, 2, \ldots, T\}$; then the agent receives a reward, also called an outcome, $X_t \in \mathbb{R}$, which is linked to the arm $A_t$. Using the Neyman-Rubin framework (Neyman, 1923; Rubin, 1974), the reward in round $t$ is defined as $X_t = \sum_{a=1}^{K} \mathbb{1}[A_t = a]X_{a,t}$, where $X_{a,t} \in \mathbb{R}$ is a potential independent outcome having a distribution $\nu_a$ with an expected reward $\mu_a$. A set of the distributions $\nu = (\nu_a)_{a \in [K]}$ is called a bandit model. The best arm $a^* = a^*(\nu)$ is defined as $\mu_{a^*} > \max_{a \neq a^*} \mu_a$, which is assumed to exist uniquely. Without loss of generality, we assume that $\mu_1 > \mu_2 \geq \ldots \geq \mu_K$, hence $a^* = 1$.

We study a strategy for the BAI problem, which recommends an arm $\hat{a}_T \in [K]$ after sequentially sampling arms for $T$ rounds. Specifically, with the sigma-algebra $\mathcal{F}_t = \sigma(A_1, X_1, \ldots, A_t, X_t)$ generated by all observations up to time $t$, we define a BAI strategy as a pair $((A_t)_{t \in [T]}, \hat{a}_T)$, where

- the sampling rule selects an arm $A_t$ for each $t$ based on past observations $\mathcal{F}_{t-1}$ (here, $A_t$ is $\mathcal{F}_{t-1}$-measurable).
- the recommendation rule estimates the best arm $\hat{a}_T$ based on observation up to time $T$ (here, $\hat{a}_T$ is $\mathcal{F}_T$-measurable).

Let $P_\nu$ and $E_\nu$ be the probability and expectation under the model $\nu$, respectively. Our goal is to find a strategy that minimizes the probability of misidentification, denoted by $P_\nu(\hat{a}_T \neq 1)$.

For a strategy, we are interested in the probability of misidentification in the BAI problem, and there are unsolved issues. Specifically, several upper and lower bounds on the probability of misidentification have been investigated; however, there remains room for improvement. Glynn and Juneja (2004) discusses the optimal arm allocation ratio in a simplified problem setting that differs from BAI problems. That study succeeds in clarifying the misidentification probability, but it is difficult to extend the results to general BAI problems with unknown parameters. Kaufmann et al. (2016) derives a problem-dependent lower bound on the misidentification probability for the two-armed BAI with a fixed budget, but a strategy that can achieve the lower bound with unknown optimal arm allocation ratio is still undetermined. In Carpentier and Locatelli (2016), they provide lower bounds on the misidentification probability for the $K$-armed bandit case for some bandit models. Even in their case, their upper and lower bounds on the misidentification probability do not match due to the effect of constant factors in the exponent. To the best of our knowledge, matching upper and lower bounds on the probability of misidentification remain an open problem in the BAI problem, when we do not have prior knowledge of the optimal arm allocation ratio of the arm draws.

In this study, we tackle this problem by developing a theoretical framework on a lower bound on the probability of misidentification. To develop the framework, we introduce two important notions: (i) A Small Gap of bandit models $\nu$, which expected rewards $\max_{a,b \in [K]} |\mu_a - \mu_b| \leq \Delta$ with a small gap $\Delta > 0$. (ii) Locally stable strategies, whose sampling rule does not change significantly with the $2\Delta$ perturbations to the expected reward. The small gap setting has been considered in BAI with fixed confidence (Jamieson et al., 2014), treatment choice (Hirano and Porter, 2009), and Bayesian BAI (Komiyama et al., 2021). Consequently, under several regularity conditions, for any bandit model with a small gap, for any consistent and locally stable strategy (for the precise definition, see Definition 2.3 in Section 2), our theoretical framework gives the following lower bound:

$$
\lim sup_{T \to \infty} - \frac{1}{T} \log P_\nu(\hat{a}_T \neq 1) \leq \sup_{(w_1, \ldots, w_K) \in W} \min_{a \in [K], \{1\}} \frac{(\mu_1 - \mu_a)^2}{2 \left( \frac{1}{I_a(\mu_a)w_1} + \frac{I_a(\mu_a)w_a}{I_a(\mu_a)w_1} \right)} + o(\Delta^2), \tag{1}
$$

where $W = \{ w \in \mathbb{R}^K_+ : \sum_{a=1}^K w_a = 1 \}$ is a $(K - 1)$-simplex, $I_a(\mu_a)$ denotes the Fisher information about the expected reward $\mu_a$, and $o(\cdot)$ is Landau’s small o notation as $\Delta \to 0$. We remark that the upper bound inequality in (1) is a lower bound on the misidentification probability, since $- \log x$ is a strictly decreasing function; that is, the larger $-(1/T) \log P_\nu(\hat{a}_T \neq 1)$ becomes, the smaller $P_\nu(\hat{a}_T \neq 1)$ becomes (Kaufmann et al., 2016). With the case $\Delta \to 0$ and $K = 2$, the derived lower bound (1) corresponds that of Kaufmann et al. (2016), hence the bound (1) is the generalization of the previous lower bound. This framework is particularly inspired by the studies in the following topics: statistical treatment rules under limit experiments with local asymptotic normality (Le Cam, 1986; van der Vaart, 1998; Manski, 2000; Hirano and Porter, 2009, 2020), and the large deviation bound for martingales (Grama and Haeusler, 2000; Fan et al., 2013, 2014).

Furthermore, we construct a strategy whose misidentification probability attains the lower bound (1), based on the developed theory. We refer to our strategy as the random sampling-augmented inverse probability weight (RS-AIPW) strategy, because of the following two coordinates: (i) a sampling rule with random sampling (RS) following an estimated optimal allocation ratio of arm draws, and (ii) a recommendation rule using the augmented inverse probability weighting (AIPW) estimator (Robins et al., 1994; Bang and Robins, 2005a), which is often used in the causal inference (Chernozhukov et al., 2018; Foster and Syrgkanis, 2019). We show that the RS-AIPW strategy is asymptotically optimal with a sufficiently small gap $\Delta$ and some condition on distribution on $\nu$, since an upper bound on its probability of misidentification attains the derived lower bound (1) (see Theorem 4.1). As a result, we present the first strategy with an upper bound matching the lower bound for locally stable strategies in the BAI problem with a fixed budget. To show this result, we prove the dominating term of the probability of misidentification is insensitive to the error due to estimation of the optimal allocation ratio since this error goes to high-order terms.

Our contribution is summarized as follows. First, we provide a new framework of the problem-dependent lower bound, which is a generalization of the bound by Kaufmann et al. (2016) for the two arms case. Next, we propose the optimal RS-AIPW strategy whose misidentification probability achieves the lower bound. As a result, we reveal the asymptotically matching upper and lower bounds under a small gap. Our small gap arguments are inspired by the limit experiment framework (Le Cam, 1986; van der Vaart, 1998), but they differ fundamentally. For technical contribution, we extend the large deviation bound for martingales by Fan et al. (2013, 2014) to show the optimality of the RS-AIPW strategy by using the martingale property of the AIPW estimator.

**Organization.** The remainder of this paper is organized as follows. In Section 2, we describe the problem-dependent lower bound and its proof. In Section 3, we discuss the optimal allocation ratio deduced from the lower bound, then we present the RS-AIPW strategy and its implementation. In Section 4, we show the performance guarantee of our
Let us define proposed RS-AIPW strategy. In Section 5, we discuss related work. Most of the proofs and numerical experiments are given in Appendix.

**Notation.** Let us define \( N_{a,t} = \sum_{s=1}^{t} \mathbb{I}[A_s = a] \). For probability distributions \( p \) and \( q \), when \( p \) is absolutely continuous with respect to \( q \), we also define the Kullback-Leibler (KL) divergence as \( KL(p, q) = \int \log\left(\frac{dp(x)}{dq(x)}\right)dp(x) \). We denote the KL divergence of Bernoulli distribution by \( d(x, y) := x \log(x/y) + (1-x) \log((1-x)/(1-y)) \) with the convention that \( d(0,0) = d(1,1) = 0 \). For each \( \nu_a \), we denote the standard deviation by \( \sigma_a \). For a density function \( f_a(x|\mu_a) \), let \( f_a(\mu|x) = \log f_a(x|\mu) \) be a log likelihood function. Its Fisher information is defined as \( I_a(\mu_a) = -\mathbb{E}_a[\ell_a(\mu_a)] \).

## 2 Problem-dependent Lower Bound and Approximation under a Small Gap

This section provides a problem-dependent lower bound under a small gap in BAI with a fixed budget. Let \( \Omega \) be a family of all possible \( \nu \). Suppose that for each \( a \in [K] \), \( \nu_a \) belongs to a (known) family of distribution with an expected reward \( \mu_a \in \mathcal{M}_a \), where \( \mathcal{M}_a \subset \mathbb{R} \) is a parameter space of \( \mu_a \). We assume that for each \( a \in [K] \), \( \forall \mu_a \in \mathcal{M}_a, |\mu_a| \leq C_\mu \) with some constant \( C_\mu > 0 \). We also assume that the distribution has a density \( f_a(x|\mu) \). A strategy is called consistent if for every choice of \( \nu \in \Omega \), \( \mathbb{P}_\nu(\hat{a}_T \neq 1) \) tends to zero as \( T \) increases to infinity.

Our lower bound derivation is based on the change-of-measure arguments, which have been extensively used mainly in the bandit literature (Lai and Robbins, 1985). Kaufmann et al. (2016) derives the following change-of-measure argument, which is the principal tool in our lower bound.

**Proposition 2.1** (Lemma 1 in Kaufmann et al. (2016)). Let \( \nu \) and \( \nu' \) be two bandit models with \( K \) arms such that for all \( a \in [K] \), \( \nu_a \) (distribution of reward of arm \( a \) for model \( \nu \) ), and \( \nu'_a \) (distribution of reward of arm \( a \) for the model \( \nu' \) ) are mutually absolutely continuous. Then,

\[
\sum_{a=1}^{K} \mathbb{E}_\nu[N_{a,T}]KL(\nu_a, \nu'_a) \geq \sup_{\mathcal{F}_T} d(\mathbb{P}_\nu(\mathcal{F}), \mathbb{P}_{\nu'}(\mathcal{F})).
\]

In this proposition, we generate a perturbed observation that is based on the modified bandit model. This “transportation” lemma gives the problem-dependent characterization of the events under a given bandit model \( \nu \) and the perturbed bandit model \( \nu' \). For example, in Theorem 12 in Kaufmann et al. (2016), the authors show that for any \( \nu \in \Omega \) with \( \mu_1 > \mu_2 \), any consistent strategy satisfies, \( \limsup_{T \to \infty} -(1/T) \log \mathbb{P}_\nu(\hat{a}_T \neq 1) \leq \inf_{\nu', \nu''} \max\{KL(\nu_1, \nu'_1), KL(\nu'_2, \nu_2)\} \). However, to the best of our knowledge, performance guarantees achieving this bound have not been proposed.

In our derivation, we first restrict the bandit models that have a small gap. Then, we further introduce a strategy class called locally stable strategies to restrict the strategy class. We then present the problem-dependent lower bound represented by the expected rewards and the Fisher information with some vanishing error terms as the gap goes to zero.

### 2.1 Restrictions on Bandit Models and Strategies

First, we restrict the classes of problems and strategies to our interests.

**Local parametrization.** First, we introduce a notion of locally parametrized bandit models where the gap between the expected rewards is within a certain range.

**Definition 2.2** (Bandit models with a small gap). For each \( \Delta > 0 \), we define the subset of the model class where the gap is smaller than \( \Delta \):

\[
S(\Delta) = \{ \nu \in \Omega : \forall a, b \in [K], |\mu_a - \mu_b| \leq \Delta \}.
\]

Our arguments are inspired by the localization arguments in BAI with fixed confidence (Jamieson et al., 2014) and limit experiment (Le Cam, 1960, 1972, 1986; van der Vaart, 1991, 1998). However, these localization arguments cannot provide the problem-dependent optimality in BAI with a fixed budget. Instead, we derive a localized problem-dependent lower bound based on the techniques developed by Lai and Robbins (1985); Graves and Lai (1997); Kaufmann et al. (2016), which are different from theirs.
**Locally stable strategy.** We introduce a class of *locally stable* strategies that are intrinsically meaningful to our interests. For each $\Delta > 0$ and $\nu \in \Omega$, define $\text{Local}_{\Delta}(\nu) = \{ \nu' \in \Omega : \forall a \in [K], |\mu_a - \mu'_a| \leq 2\Delta \}$. The following definition represents a class of stable strategies under a bandit model with a small gap.

**Definition 2.3** (Locally stable strategies). A strategy is locally stable if there exists a function $\eta(\Delta) > 0$ with $\lim_{\Delta \to 0} \eta(\Delta) = 0$ such that for any $\Delta > 0$, $\nu \in \mathcal{S}(\Delta)$, and for all models $\nu' \in \text{Local}_{\Delta}(\nu)$,

$$\forall a \in [K], \quad \limsup_{T \to \infty} \frac{|E_{\nu}[N_a,T] - E_{\nu'}[N_a,T]|}{T} \leq \eta(\Delta).$$

We introduced this definition to apply the change-of-measure argument (Proposition 2.1) to fixed-budget BAI with $K$ arms. Originally, the argument is applied to the two-arm ($K=2$) BAI problem by Kaufmann et al. (2016), with the help of the symmetric restriction $N_{1,T} = T - N_{2,T}$. However, we cannot apply Proposition 2.1 when $K \geq 3$, since the symmetric restriction is no longer valid. To solve this limitation, we introduce the local stability, which restricts the degrees of freedom of strategies to allow for analysis.

Note that the existence of locally stable strategies is guaranteed, as a strategy with a uniform sampling rule is locally stable. We will see (in Section 4) that the strategy follows the optimal allocation $w^*$ (see Section 3 for the definition) in expectation, which is continuous with respect to $\mu_a$, is locally stable. In particular, the proposed RS-AIPW strategy is locally stable.

### 2.2 Derivation of Lower Bound under a Small Gap

Under these local characterizations, we derive a problem-dependent lower bound. For each $\nu \in \Omega$, let $\text{Alt}_{\Delta}(\nu)$ be the set of local alternative models defined as:

$$\text{Alt}_{\Delta}(\nu) = \{ \nu' \in \Omega : a^*(\nu') \neq 1, \forall a \in [K], |\mu_a - \mu'_a| \leq 2\Delta \};$$

that is, it is a subset of the slightly perturbed bandit models whose best arm is not 1. Note that $\text{Alt}_{\Delta}(\nu) \subseteq \text{Local}_{\Delta}(\nu)$.

Using a log likelihood $\ell_a(\mu|x)$, we assume the following regularity conditions on the Fisher information $I_a(\mu)$.

**Assumption 2.4.** Let $M^a_0$ be the interior of $M_a$. For each $a \in [K]$, (i) the support $\{ x : f_a(x|\mu_a) > 0 \}$ does not depend on the parameter $\mu_a$; (ii) if $\mu_a \in M^a_0$, there exists the Fisher information $I_a(\mu_a)$ and a positive constant $C_I$ such that $\max(1/I_a(\mu_a), I_a(\mu_a)) < C_I$; (iii) the log likelihood function is thrice differentiable with respect to $\mu_a \in M_a$; (iv) $\mathbb{E}_a[\ell_a(\mu_a)] = 0$, $\mathbb{E}_a[\ell'_a(\mu_a)] = -I_a(\mu_a)$; (v) there exist constants $C, C' > 0$ such that for all $\mu_a \in M^a_0$, there exists a neighborhood $U(\mu_a)$ such that for all $\tilde{\mu} \in U(\mu_a)$, $\mathbb{E}_a[\ell'_a(\tilde{\mu})] \leq C$ and $|I_a(\tilde{\mu}) - I_a(\mu_a)| \leq C' |\tilde{\mu} - \mu_a|$.

Then, based on the preliminaries above, we prove the following problem-dependent lower bound.

**Lemma 2.5.** Under Assumption 2.4, for any $\Delta > 0$ and $\nu \in \mathcal{S}(\Delta)$, for any consistent and locally stable strategy,

$$\limsup_{T \to \infty} -\frac{1}{T} \log \mathbb{P}_\nu(\hat{\alpha}_T \neq 1) \leq \sup_{w \in \mathcal{W}} \inf_{\nu' \in \text{Alt}_{\Delta}(\nu)} \sum_{a=1}^K w_a \left( \frac{\mu'_a - \mu_a}{2} \right)^2 + \Delta^2 KC_{\mu,I}(\eta(\Delta) + \Delta),$$

where $C_{\mu,I}$ is a universal constant depending on $C_{\mu}$ and $C_I$.

**Proof.** For each $\nu' \in \text{Alt}_{\Delta}(\nu)$, from Proposition 2.1, the following holds $\sum_{a=1}^K \mathbb{E}_{\nu'}[N_a,T] \text{KL}(\nu'_a, \nu_a) \geq \sup_{\mathcal{E} \in \mathcal{E}_T} d(\mathbb{P}_{\nu'}(\mathcal{E}), \mathbb{P}_{\nu}(\mathcal{E}))$. Let $\mathcal{E} = \{ \hat{\alpha}_T = 1 \}$. Because we assume that the strategy is consistent for both models and from the definition of $\text{Alt}_{\Delta}(\nu)$, for each $\varepsilon \in (0,1)$, there exists $t_0(\varepsilon)$ such that for all $T \geq t_0(\varepsilon)$, $\mathbb{P}_{\nu'}(\mathcal{E}) \leq \varepsilon \leq \mathbb{P}_{\nu}(\mathcal{E})$. Then, for all $T \geq t_0(\varepsilon)$, $\sum_{a=1}^K \mathbb{E}_{\nu'}[N_a,T] \text{KL}(\nu'_a, \nu_a) \geq d(\varepsilon, 1 - \mathbb{P}_{\nu}(\hat{\alpha}_T \neq 1)) = $
The exponential family is defined as $\mathcal{F}_\Theta = \{ \nu\mid \nu = \exp(\Theta' x - b_\Theta(x)) \}$, where $\Theta$ is a compact subset of $\mathbb{R}$, $\xi$ is some reference measure on $\mathbb{R}$, and $b_\Theta : \Theta \to \mathbb{R}$ is a convex, twice differentiable function. Then, for any $\mu, \mu' \in \Theta$, $\nu_a$ is the unique distribution in $\mathcal{P}_a^{\exp}$ with expectation $\mu_a$. We assume that for all $\nu_a \in \mathcal{P}_a^{\exp}$, $X_{a,t}$ is a sub-exponential random variable. For a Gaussian distribution with heterogeneous variance and distribution belonging to a canonical exponential family, the inverse of the Fisher information matches with the variance; that is, $\mathbb{E}_\nu[\{X_{a,t} - \mu_a\}^2] = 1/I_a(\mu_a)$. Under Assumption 2.4, the Fisher information is bounded by constant $C_I$:

$$\forall a \in [K], \max\{I_a(\mu_a), 1/I_a(\mu_a)\} \leq C_I \quad (\text{Lehmann and Casella, 1998}).$$

Note that the family of distributions for each arm can vary. For example, while $\nu_1$ follows a Gaussian distribution, $\nu_2$ can follow a Bernoulli distribution.

In Section 3, we give specific forms of the bound when each bandit model follows a Gaussian distribution with unknown heterogeneous variance or canonical one-parameter exponential family.

### 3 Proposed Strategy: The RS-AIPW Strategy

In this section, we define our BAI strategy, which consists of sampling and recommendation rules. In this study, we focus on the case where the bandit model $\nu_a$ is a Gaussian distribution with unknown variance or belongs to a canonical one-parameter exponential family. A canonical one-parameter exponential family is defined as $\mathcal{P}_a^{\exp} = \{ \nu_a^\Theta : \Theta \in \Theta_a, d\nu_a^\Theta = \exp(\Theta_\xi - b_\Theta(\xi)) \}$, where $\Theta_a$ is a compact subset of $\mathbb{R}$, $\xi$ is some reference measure on $\mathbb{R}$, and $b_\Theta : \Theta_a \to \mathbb{R}$ is a convex, twice differentiable function. Then, for any $\mu, \mu' \in \{ \mu \in \Theta_a : \xi = \Theta_a \text{ s.t. } \mu = \xi(a) \}$, $\nu_a$ is the unique distribution in $\mathcal{P}_a^{\exp}$ with expectation $\mu_a$. We assume that for all $\nu_a \in \mathcal{P}_a^{\exp}$, $X_{a,t}$ is a sub-exponential random variable. For a Gaussian distribution with heterogeneous variance and distribution belonging to a canonical exponential family, the inverse of the Fisher information matches with the variance; that is, $\mathbb{E}_\nu[\{X_{a,t} - \mu_a\}^2] = 1/I_a(\mu_a)$. Under Assumption 2.4, the Fisher information is bounded by constant $C_I$:

$$\forall a \in [K], \max\{I_a(\mu_a), 1/I_a(\mu_a)\} \leq C_I \quad (\text{Lehmann and Casella, 1998}).$$

Note that the family of distributions for each arm can vary. For example, while $\nu_1$ follows a Gaussian distribution, $\nu_2$ can follow a Bernoulli distribution.
Corollary 3.1. Under Assumption 2.4, if each bandit model \( \nu_a \) is a Gaussian distribution with unknown heterogeneous variance or belongs to a canonical one-parameter exponential family, then for any locally stable consistent strategy,

\[
\limsup_{T \to \infty} \frac{1}{T} \log P_{\nu}(\hat{\Delta} \neq 1) \leq C \sum_{a \not= 1} \frac{1}{2\sigma_a^2} \min_{a \not= 1} \frac{(\mu_1 - \mu_2)^2}{2(\sigma_1^2 + \sigma_2^2)} + o(\Delta^2).
\]

Based on the result of Section 2 and \( \sigma_a^2 = 1/I_a(\mu_a) \), we define the optimal allocation \( w^* \) as \( w^* = \arg \max_{a \not= 1} \frac{1}{2(\sigma_1^2 + \sigma_2^2)} \). This optimal allocation is unknown when the variances are unknown; therefore, to use this ratio, we need to estimate it from observations during the trials. In each trial, our sampling rule randomly draws an arm following an estimated optimal allocation ratio; that is, we pull an arm with probability identical to the estimated optimal allocation ratio (optimal allocation probability). In final round \( T \), we recommend an arm with the highest estimated expected reward. Here, we estimate the expected reward using the AIPW estimator, which is known to reduce the sensitivity of the estimation error of the optimal allocation ratio to the asymptotic variance. Based on these rules, we refer to this as the RA-AIPW strategy. Define for each \( a \geq 2 \), \( G_a(w_1^*, w_a^*) = \frac{(\mu_1 - \mu_2)^2}{2(\sigma_1^2 + \sigma_2^2)} \).

When the optimality is attained, it is well-known that (see, e.g., Chen et al. (2000); Glynn and Juneja (2004)) the following equations are satisfied:

\[
\forall a, b \in [K], a, b \geq 2, \quad G_a(w_1^*, w_a^*) = G_b(w_1^*, w_b^*) \quad \text{and} \quad \frac{\partial G_a(w_1^*, w_a^*)}{\partial w_1} \Big|_{w_1 = w_1^*, w_a = w_a^*} = \frac{(\sigma_1 w_1^*)^2}{(\sigma_a w_a^*)^2},
\]

so that \( w_1^* = \frac{\sigma_a}{\sum_{a=2}^{\infty} w_a^2} \). However, the computation of the optimal allocation requires convex programming. Inspired by the arguments in Garivier and Kaufmann (2016) Theorem 5, we simplify the condition for the optimal allocation.

Lemma 3.2. The optimal allocation \( w^* \) is given as

\[
w_1^* = \frac{1}{1 + \sum_{a=2}^{\infty} (1/\psi_a(y^*))} \quad \text{and} \quad w_a^* = \frac{1}{1 + \sum_{a=2}^{\infty} (1/\psi_a(y^*))},
\]

where for each \( a \in [K] \), \( \psi_a(y) = ((\mu_1 - \mu_a)^2 - 2y\sigma_a^2)/(2\sigma_a^2 y) \) and \( y^* \) is the unique solution of the equation:

\[
\sum_{a=2}^{\infty} \frac{\sigma_a^2}{\sigma_a^2 \psi_a(y^*)} = 1.
\]

Besides, \( F(y) = \sum_{a=2}^{\infty} \frac{\sigma_a^2}{\sigma_a^2 \psi_a(y^*)} \), defined on \( (0, (\mu_1 - \mu_2)^2/(2\sigma_1^2)) \), is a strictly increasing function such that \( \lim_{y \to 0} F(y) = 0 \) and \( \lim_{y \to (\mu_1 - \mu_2)^2/(2\sigma_1^2)} F(y) = \infty \).

The proof is presented in Appendix D. Therefore, the optimal allocation \( w^* \) can be obtained by the simple bisection method. Such techniques are often found in the literature on sequential decision making (e.g., Chan and Lai (2006)).

3.1 Sampling Rule with Estimated Optimal Allocation Ratio

We estimate \( \mu_a \) and \( \sigma_a^2 \) for \( a \in [K] \) in round \( t \) as

\[
\hat{\mu}_a, t = \left\{ \begin{array}{ll} C_\mu & \text{if } C_\mu < \hat{\mu}_a, t, \\
\hat{\mu}_a, t & \text{if } -C_\mu \leq \hat{\mu}_a, t \leq C_\mu, \\
-C_\mu & \text{if } \hat{\mu}_a, t < -C_\mu, \end{array} \right. \quad \hat{\sigma}_{a, t}^2 = \left\{ \begin{array}{ll} C_{\sigma_a^2} & \text{if } C_{\sigma_a^2} < \hat{\sigma}_{a, t}^2, \\
\hat{\sigma}_{a, t}^2 & \text{if } 1/C_{\sigma_a^2} \leq \hat{\sigma}_{a, t}^2 \leq C_{\sigma_a^2}, \\
1/C_{\sigma_a^2} & \text{if } \hat{\sigma}_{a, t}^2 < 1/C_{\sigma_a^2}, \end{array} \right. \quad (2)
\]

where for each \( t \in \{1, 2, \ldots, T\} \), we define \( \hat{\mu}_a, t = \sum_{s=1}^{t-1} \frac{1}{\sum_{a=1}^{t-1} \sum_{[A_s] = a} 1} \sum_{s=1}^{t-1} \frac{1}{\sum_{a=1}^{t-1} \sum_{[A_s] = a} 1} X_{a, s}, \) and \( \hat{\sigma}_{a, t}^2 = \hat{\sigma}_{a, s}^2 - \hat{\mu}_{a, t}^2 \). Let \( \hat{a}_t \in \text{arg max}_{a \in [K]} \hat{\mu}_a, t \) (ties are broken arbitrarily). When the empirical best arm is unique; that is, \( \hat{\mu}_{\hat{a}_t, t} > \max_{a \not= \hat{a}_t} \hat{\mu}_a, t \), we estimate \( w^* \) as

\[
w_a, t = \begin{cases} \frac{1}{1 + \sum_{a=2}^{\infty} (1/\psi_a(y^*))} & \text{if } a = \hat{a}_t, \\
\frac{1}{1 + \sum_{a=2}^{\infty} (1/\psi_a(y^*))} & \text{otherwise}, \end{cases}
\]

where \( \psi_b, t(y) = (\hat{\mu}_{\hat{a}_t, t} - \hat{\mu}_{b, t})^2 - 2y\hat{\sigma}_{a, t}^2 \).
RS-AIPW strategy

**Parameter:** Positive constants $C_{\mu}, C_{\sigma^2}, C_w$.

**Initialization:**
At $t = 1, 2, \ldots, K$, select $A_t = t$ and set $w_{a,t} = \frac{1}{K}$ for $a \in [K]$.

**for** $t = K + 1$ to $T$ **do**
- Construct $\hat{\mu}_{a,t}$ and $\hat{\sigma}^2_{a,t}$ following (2).
- Compute $(w_{a,t})_{a \in [K]}$ following (3).
  **if** $\forall a \in [K], \ w_{a,t} > C_w$ **then**
  - Select $A_t = a$ with probability $w_{a,t}$ for all $a \in [K]$.
  **else**
  - Select $A_t = a$ with probability $1/K$ for all $a \in [K]$.
  **end if**
- Construct $\hat{\mu}_{a,T}$ and $\hat{\sigma}^2_{a,T}$ following (2).
- Construct $\hat{\mu}_{a,T}^{\text{AIPW}}$ following (4).
- Recommend $\hat{a}_T \in \arg \max_{a \in [K]} \hat{\mu}_{a,T}^{\text{AIPW}}$.

3.2 Recommendation Rule with the AIPW Estimator

For each $a \in [K]$, we define the AIPW estimator as

$$\hat{\mu}_{a,T}^{\text{AIPW}} = \frac{1}{T} \sum_{t=1}^{T} \hat{X}_{a,t}, \quad \hat{X}_{a,t} = \frac{1[A_t = a](X_{a,t} - \hat{\mu}_{a,t})}{w_{a,t}} + \hat{\mu}_{a,t}.$$  \hspace{1cm} (4)

We recommend the arm based on the value of the AIPW estimator as $\hat{a}_T \in \arg \max_{a \in [K]} \hat{\mu}_{a,T}^{\text{AIPW}}$, where the ties are broken arbitrary at random.

Both $\hat{\mu}_{a,T}$ and $(\hat{\mu}_{a,t})_{t=1}^{T}$ are estimators of $\mu_a$. As explained, the AIPW estimator $\hat{\mu}_{a,T}^{\text{AIPW}}$ has the following advantages. First, its components satisfy the martingale property, and hence, allow us to use the large deviation bound shown in Theorem 4.2. On the other hand, since $\hat{\mu}_{a,t}$ does not have the martingale property, it is difficult to make the theoretical analysis. Moreover, we can construct other estimators with a martingale property, such as the inverse probability weighting (IPW) estimator. (Horvitz and Thompson, 1952) by setting $\hat{\mu}_{a,t} = 0$, but their asymptotic variance can be larger than that of the AIPW estimator.

3.3 Implementation of the RS-AIPW Strategy

We show the pseudocode of the RS-AIPW strategy in Algorithm 1. We note that $C_{\mu}, C_{\sigma^2}$, and $C_w$ are introduced for the technical purpose so that the estimators are bounded. Therefore, any large positive value (or small enough positive value for $C_w$) can be assumed. Formally, we assume that for each $a \in [K], \ |\mu_a| \leq C_{\mu}, \ \max\{\sigma^2_a, 1/\sigma^2_a\} \leq C_{\sigma^2}, \ w^\ast_a > C_w$. In the pseudocode, for brevity, only the first $K$ rounds are used for initialization. In practice, the number of initialization rounds can be adjusted for each application.

In Appendix K, we show simulation studies to investigate the empirical performance.

4 Asymptotic Optimality of the RS-AIPW Strategy

This section is devoted to the performance guarantee of the RS-AIPW strategy. The following theorem provides the performance guarantee of the proposed RS-AIPW strategy. We show that the strategy is asymptotically optimal.

**Theorem 4.1** (Performance guarantee of the RS-AIPW strategy). For any $\Delta > 0$, for any $\nu \in S(\Delta)$, under the RS-AIPW strategy,

$$\lim \inf_{T \to \infty} \frac{1}{T} \log \mathbb{P}_\nu(\hat{a}_T \neq 1) + C_{\mu,\sigma^2}(\Delta^3 + \Delta^4) \geq \sup_{a \in [K], \ a \neq 1} \min_{w \in \mathbb{W}} \frac{(\mu_1 - \mu_a)^2}{2(\sigma^2_1/w_1 + \sigma^2_a/w_a)},$$

where $C_{\mu,\sigma^2}$ is a universal constant depending on $C_{\mu}, C_{\sigma^2}$.

When for each $a \in [K]$, the bandit model $\nu_a$ follows a Gaussian distribution with heterogeneous variance or belongs to a canonical exponential family, we have $\sigma^2_a = 1/I_a(\mu_a)$ (Lehmann and Casella, 1998); therefore, as $\Delta \to 0$, Theorem 4.1 matches the lower bound in Theorem 2.7.
In BAI, we are interested in the evaluation of the exponentially small probability of misidentification and our result can be regarded as a Gaussian approximation of the probability of misidentification. For this purpose, the CLT cannot provide an answer because it gives an approximation around $1/\sqrt{T}$ of the expected reward, and fails to provide the evaluation for the regime with constant deviation from the expected reward. On the other hand, owing to the non-stationary adaptive process in BAI, it is also difficult to apply the standard large deviation bound (Dembo and Zeitouni, 2009) to the simple sample average. For example, Gärtner-Ellis theorem (Gärtner, 1977; Ellis, 1984) provides a large deviation bound for dependent samples, but it requires the existence of the logarithmic moment generating function, which is not easy to be guaranteed for the samples in BAI. For these problems, we derive a novel Cramér large deviation bounds for martingales of independent interest by extending the results by Grama and Haeusler (2000) and Fan et al. (2013, 2014). Using the novel bound and the AIPW estimator, as the gap $\Delta$ goes to zero, the performance guarantee matches the lower bound. The remaining part of this section provides the proof of Theorem 4.1.

4.1 Cramér’s Large Deviation Expansions for the AIPW Estimator

First, we present a novel large deviation bound for martingales. Our large deviation bound is inspired by the studies Grama and Haeusler (2000) and Fan et al. (2013, 2014). Note that their original large deviation bound is only applicable to martingales whose conditional second moment is bounded by any accuracy deterministically in advance. However, in BAI, we can only bound the conditional second moment by any accuracy in a given random path. This randomness prevents us from applying the original results of Grama and Haeusler (2000) and Fan et al. (2013, 2014). In the following argument, we show a large deviation bound for martingales given by the BAI strategy under the mean convergence of the unconditional second moment.

Fix any $a \in [K] \setminus \{1\}$. Let us define $\Delta_a = \mu_1 - \mu_a$ and

$$\xi_t = \frac{X_{1,t} - \hat{X}_{a,t} - (\mu_1 - \mu_a)}{\sqrt{T (\sigma_1^2/w_1^2 + \sigma_a^2/w_a^2)}} = \frac{\hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a}{\sqrt{T \hat{\sigma}_a}},$$

where $\hat{\sigma}_a = \sqrt{\sigma_1^2/w_1^2 + \sigma_a^2/w_a^2}$.

For $t \in [T]$, let us also define $Z_t = \sum_{s=1}^t \xi_s$, $W_0 = 0$, and $W_t = \sum_{s=1}^t E_\nu [\xi_s^2 | F_{t-1}]$. Here, $\{ (\xi_s, F_t) \}_{t=1}^T$ is a martingale difference sequence (Appendix E), using the fact that $\hat{\mu}_{a,t}$ and $w_{a,t}$ are $F_{t-1}$-measurable random variables. Let us also define $V_T = E_\nu \left[ \sum_{s=1}^T E_\nu [\xi_s^2 | F_{t-1}] - 1 \right]$ and denote the cumulative distribution function of the standard normal distribution by $\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp \left( -\frac{t^2}{2} \right) dt$. We have the following theorem on the tail probability of $Z_T = \sum_{s=1}^T \xi_s$.

**Theorem 4.2.** Suppose that the following condition holds:

**Condition A:** $\sup_{1 \leq t \leq T} E_\nu \left[ \exp \left( C_0 \sqrt{T} | \xi_t \right) \right. | F_{t-1}] \leq C_1$ for some positive constants $C_0, C_1$.

Then, there exist constants $c_1, c_2 > 0$ such that, for all $1 \leq u \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_1}{8CT}} \right\}$,

$$\Pr_\nu (Z_T \leq -u) \leq c_1u \exp \left( c_2 \left( \frac{u^3}{\sqrt{T}} + \frac{u^4}{T} + u^2 V_T \right) \right),$$

where the constants $c_1, c_2$ depend on $C_0$ and $C_1$ but do not depend on $\{ (\xi_t, F_t) \}_{t=1}^T$, $\nu$, and the bandit model $\nu$.

From Theorem 4.2, if $\lim_{T \to \infty} V_T = 0$ and $\frac{\Delta_a}{\hat{\sigma}_a} \leq \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_1}{8CT}} \right\}$ as $\Delta_a \to 0$, for $u = \sqrt{T} \frac{\Delta_a}{\hat{\sigma}_a}$ and $\Pr_\nu \left( Z_T \leq -\sqrt{T} \frac{\Delta_a}{\hat{\sigma}_a} \right) = \Pr_\nu \left( \sum_{t=1}^T \frac{X_{1,t} - \hat{X}_{a,t} - \Delta_a}{\sqrt{T \hat{\sigma}_a}} \leq -\sqrt{T} \frac{\Delta_a}{\hat{\sigma}_a} \right) = \Pr_\nu (\hat{\mu}_{1,T}^{\mathrm{AIPW}} \leq \hat{\mu}_{a,T}^{\mathrm{AIPW}})$, the probability that we fail to make the correct arm comparison is bounded as follows.

$$\Pr_\nu \left( \hat{\mu}_{1,T}^{\mathrm{AIPW}} \leq \hat{\mu}_{a,T}^{\mathrm{AIPW}} \right) \leq c_1 \sqrt{T} \frac{\Delta_a}{\hat{\sigma}_a} \exp \left( c_2 T \left( \frac{\Delta_a}{\hat{\sigma}_a} \right)^3 + \left( \frac{\Delta_a}{\hat{\sigma}_a} \right)^4 + \left( \frac{\Delta_a}{\hat{\sigma}_a} \right)^2 V_T \right).$$

(5)

Here, we provide the proof sketch of Theorem 4.2. The formal proof is shown in Appendix H.

**Proof sketch of Theorem 4.2.** Let us define $r_t(\lambda) = \exp (\lambda \xi_t) / \mathbb{E} [\exp (\lambda \xi_t)]$. Then, we apply the change-of-measure in Fan et al. (2013, 2014) to transform the bound. In Fan et al. (2013, 2014), the proof is complete up to this
procedure. However in our case, unlike their settings, the second moment is also a random variable. Because of the randomness, there remains a term $\mathbb{E} \left[ \exp \left( \frac{1}{\sqrt{2\pi}(1+u)} \right) \mathbb{I} \left( \sum_{t=1}^{T} \xi_t \right) \right] / (\prod_{t=1}^{T} \mathbb{E} \left[ \exp \left( \frac{\lambda}{\sqrt{2\pi}(1+u)} \mathbb{I} \left( \sum_{t=1}^{T} \xi_t \right) \right) \right])$, where $\lambda$ is some positive function of $u$. Therefore, we next consider the bound of the conditional second moment of $\xi_t$ to apply $L^r$-convergence theorem (Proposition A.3). With some computation, we complete the proof.

### 4.2 Gaussian Approximation under a Small Gap

Finally, we consider an approximation of the large deviation bound. Here, $\Phi(-\lambda \xi_t)$ is bounded as $\frac{1}{\sqrt{2\pi}(1+u)} \exp \left( -\frac{\lambda^2}{2} \right) \leq \Phi(-\lambda \xi_t) \leq \frac{1}{\sqrt{2\pi}(1+u)} \exp \left( -\frac{\lambda^2}{2} \right)$, $u \geq 0$ (see Fan et al. (Section 2.2., 2013)). By combining this bound with Theorem 4.2 and (3), we have the following corollary.

**Lemma 4.3.** Suppose that $\text{Condition A (in Theorem 4.2)}$ and the following conditions hold:

- **Condition B:** $\frac{\Delta^2}{\xi^2} \leq \min \{ C_0 / 4, \sqrt{3C_2^2}, 8C_1 \}$;
- **Condition C:** $\lim_{T \to \infty} V_T = 0$.

Then $\liminf_{T \to \infty} -\left( 1 / T \right) \log \mathbb{P}_T \left( \xi_{AIPW}^1 T \leq \hat{\xi}_{AIPW}^1 T \right) \geq \frac{\Delta^2}{\xi^2} - c \left( \frac{\Delta a}{\sigma_a} \right)^3 + \left( \frac{\Delta a}{\sigma_a} \right)^4$, where $c > 0$ is some constant.

This approximation can be thought of as a Gaussian approximation because the probability is represented by $\exp \left( -\frac{\Delta^2}{2\xi^2} \right)$. Condition B is satisfied as $\Delta \to 0$. To use Lemma 4.3, we need to show that Conditions A and C hold. First, the following lemma states that Condition A holds with the constants $C_0$ and $C_1$, which are universal to the problems in $\Omega$.

**Lemma 4.4.** For each $C_0 \geq 0$, there exists a positive constant $C_1$, which depends on $C_0, C_\sigma^2, C_\mu, C_w$, such that for any $\mu_1 \in M_1, \mu_a \in M_a$, $\sup_{t \in [T]} \mathbb{E}_t \left[ \exp \left( C_0 \sqrt{T} \xi_t \right) \right] \leq C_1$.

Next, regarding Condition C, we introduce the following lemma for the convergence of $V_T$.

**Lemma 4.5.** Under the RS-AIPW strategy, for any $\nu \in \Omega$, $\lim_{T \to \infty} V_T = 0$: that is, for any $\delta > 0$, there exists $T_0$ such that for all $T > T_0$, $\mathbb{E}_t \left[ \sum_{t=1}^{T} \mathbb{E}_t \left[ \xi_t^2 \right] \right] \leq \delta$.

Finally, the proof of Theorem 4.1 is completed as follows:

$$
\liminf_{T \to \infty} -\frac{1}{T} \log \mathbb{P}_T \left( \hat{a}_T \neq 1 \right) \geq \liminf_{T \to \infty} -\frac{1}{T} \log \sum_{a \neq 1} \mathbb{P}_T \left( \hat{a}_{AIPW}^1 T \geq \hat{a}_{AIPW}^1 T \right) \\
= \liminf_{T \to \infty} -\frac{1}{T} \log \left( K - 1 \right) \max_{a \neq 1} \mathbb{P}_T \left( \hat{a}_{AIPW}^1 T \geq \hat{a}_{AIPW}^1 T \right) \geq \min_{a \neq 1} \frac{\Delta^2}{2\Delta^2 \sigma_a^2} - c \left( \frac{\Delta a}{\sigma_a} \right)^3 + \left( \frac{\Delta a}{\sigma_a} \right)^4 \\
\geq \sup_{w \in W} \min_{a \neq 1} \frac{(\mu_1 - \mu_a)^2}{2(\sigma_a^2 / w^2 + \sigma_a^2 / w_a)} - C_{\mu, \sigma^2} (\Delta^2 + \Delta^4).
$$

The proofs of Lemma 4.4 and Lemma 4.5 are shown in Appendix F and G, respectively.

### 4.3 Discussion on the RS-AIPW Strategy

We make several comments regarding the RS-AIPW Strategy and its performance guarantee.

First, we show that the RS-AIPW strategy is locally stable. For this purpose, we prove that the expected allocation of the arm draw converges to the optimal allocation $w^*$.

**Lemma 4.6.** Under the RS-AIPW strategy, for all $a \in [K]$, $\lim_{T \to \infty} \mathbb{E}_t \left[ w^*_T \right] = w^*_a$.

The proof of Lemma 4.6 is presented in Appendix I. From Lemma 3.2, it is not difficult to see that the optimal allocation $w^*$ is continuous with respect to $(\mu_1, \ldots, \mu_K)$ (in fact, it is differentiable). Therefore, for any $\varepsilon > 0$, there exists some strictly increasing function $\Delta(\varepsilon)$ defined on $[0, 2]$ such that for all models $\nu' \in \text{Local}_\Delta(\nu)$ and $a \in [K]$, $\lim_{T \to \infty} \left| \mathbb{E}_t \left[ w^*_T \right] - \mathbb{E}_t \left[ w^*_T \right] \right| \leq \varepsilon$. Defining $\eta(\Delta)$ as the inverse of $\Delta(\varepsilon)$, we conclude that the strategy follows the optimal allocation $w^*$ in expectation, or in particular, the RS-AIPW strategy is locally stable.

Second, we remark that the control of the second moment of the martingale difference sequence, $\xi_t$, is accomplished by using the AIPW estimator. For instance, the large deviation bounds can also be applied to the IPW estimator;
however, in this case, the performance guarantee would not be optimal. This is because the asymptotic variance of the AIPW estimator is smaller than that of the IPW estimator, which is a well-known property in causal inference (Chernozhukov et al., 2018).

Furthermore, for our proof, the AIPW estimator is necessary for the recommendation rule only. As long as $V_T \to 0$ is satisfied, any sampling rule suffices to establish the optimal strategy. For example, one can easily modify the Track-and-Stop strategy in Garivier and Kaufmann (2016) to obtain the tracking-based strategy for the fixed-budget BAI.

5 Discussion and Related Work

Audibert et al. (2010) proposes the UCB-E and Successive Rejects (SR) strategies. Using the complexity terms $H_1 = \sum_{a \in [K] \setminus \{1\}} 1/\Delta_a^2$ and $H_2 = \max_{a \in [K] \setminus \{1\}} a/\Delta_a^2$, where $\Delta_a = \mu_1 - \mu_a$, they prove the upper bound on the probabilities of misidentification of the forms $\exp(-T/(18H_1))$ and $\exp(-T/((\log K)H_2))$, for UCB-E with the input $a$ (upper bound on $H_1$) and SR, respectively.

Carpentier and Locatelli (2016) discusses the optimality of the method proposed by Audibert et al. (2010) by an effect of constant factors in the exponent for some bandit models. More precisely, they considered $K$ Bernoulli bandit models. The first model is created as $\mu_1 = 1/2$ and $\mu_a = 1/2 - a/(4K)$. The $k$-th ($k = \{2, \ldots, K\}$) model is defined as replacing the average value of arm $a$ as $\mu_a = 1/2 + a/(4K)$. They proved the lower bound on the probability of misidentification of the form: $\exp(-(200T)/((\log K)H_1))$ for at least one of the instances. Their results are complementary to ours because we consider the model when $\Delta$ is small while we keep $K$ fixed.

The difficulty in discussing the optimality is also suggested by Kasy and Sautmann (2021), which attempts to show the optimality of a variant of the TTTS called exploration sampling. The authors state that the exploration sampling achieves the problem-dependent lower bound under a large gap by using the arguments of Glynn and Juneja (2004), but Ariu et al. (2021) shows a counterexample based on the results of Carpentier and Locatelli (2016).

Komiyama et al. (2021) discusses the optimality of Bayesian simple regret minimization, which is closely related to BAI in a Bayesian setting. They showed that parameters with a small gap make a significant contribution to Bayesian simple regret.

In adaptive experiments for efficient average treatment effect estimation, the AIPW estimator has also been used (van der Laan, 2008; Kato et al., 2020). Hahn et al. (2011) introduces this line of research and insists that the limit experiment framework provides an optimality. However, as discussed in Appendix J.2, in the arm choice problem, the notion of optimality is not complete. We introduce other related work in Appendix J.

6 Conclusion

We characterized the optimal probability of misidentification for BAI with a fixed budget when the gap among the expected rewards are small. Our novel problem-dependent lower bound on the misidentification probability reveals the optimal allocation of the expected number of arm draws, and the allocation is specific to each bandit model. The proposed RS-AIPW strategy has a sampling rule, which makes use of the optimal allocation guided by the lower bound. For the recommendation rule, we introduced the AIPW estimator, used in the causal inference field and forms a martingale difference sequence. With the help of a new large deviation expansion we developed, we gave the performance guarantee matching the lower bound under a small gap. Our result provides insight into long-standing open problems in the MAB field.

A Preliminaries

A.1 Mathematical Tools

Definition A.1. [Uniformly Integrable, Hamilton (1994), p. 191] A sequence \( \{A_t\} \) is said to be uniformly integrable if for every \( \epsilon > 0 \) there exists a number \( c > 0 \) such that
\[
\mathbb{E}_\nu[|A_t| \cdot I(|A_t| \geq c)] < \epsilon
\]
for all \( t \).

The following proposition is from Hamilton (1994), Proposition 7.7, p. 191.

Proposition A.2 (Sufficient Conditions for Uniform Integrability). (a) Suppose there exist \( r > 1 \) and \( M < \infty \) such that \( \mathbb{E}_\nu[|A_t|^r] < M \) for all \( t \). Then \( \{A_t\} \) is uniformly integrable. (b) Suppose there exist \( r > 1 \) and \( M < \infty \) such that \( \mathbb{E}_\nu[|b|^r] < M \) for all \( t \). If \( A_t = \sum_{j=-\infty}^{\infty} h_j b_{t-j} \) with \( \sum_{j=-\infty}^{\infty} |h_j| < \infty \), then \( \{A_t\} \) is uniformly integrable.

Proposition A.3 (\( L^r \) Convergence Theorem, p 165, Loeve (1977)). Let \( 0 < r < \infty \), suppose that \( \mathbb{E}_\nu[|a_n|^r] < \infty \) for all \( n \) and that \( a_n \xrightarrow{P} a \) as \( n \to \infty \). The following are equivalent:

(i) \( a_n \to a \) in \( L^r \) as \( n \to \infty \);

(ii) \( \mathbb{E}_\nu[|a_n|^r] \to \mathbb{E}_\nu[|a|^r] < \infty \) as \( n \to \infty \);

(iii) \( \{|a_n|^r, n \geq 1\} \) is uniformly integrable.

Proposition A.4 (Strong Law of Large Numbers for Martingales, p 35, Hall et al. (1980)). Let \( \{S_n = \sum_{i=1}^n X_i, \mathcal{H}_n, n \geq 1\} \) be a martingale and \( \{U_n, n \geq 1\} \) a nondecreasing sequence of positive r.v. such that \( U_n \) is \( \mathcal{H}_{n-1} \)-measurable. Then,
\[
\lim_{n \to \infty} U_n^{-1} S_n = 0
\]
almost surely on the set \( \{\lim_{n \to \infty} U_n = \infty, \sum_{i=1}^\infty U_i^{-1} \mathbb{E}[|X_i| |\mathcal{H}_{i-1}] < \infty\} \).

B Approximation of KL-divergence by Fisher Information

Lemma B.1. There exists a constant \( C > 0 \) such that under Assumption 2.4, for each \( a \in [K] \), for any \( \mu_a, \mu'_a \in \mathcal{M}_n^o \) with \( \mu_a - \mu'_a \leq \Delta \), if \( \Delta \) is sufficiently small such that with the neighborhood \( U(\mu_a) \) defined in Assumption 2.4 (v), \( \mu'_a \in U(\mu_a) \), the following holds,
\[
\left| \text{KL}(\nu'_a, \nu_a) - \frac{(\mu'_a - \mu_a)^2 \ell_a(\mu_a)}{2} \right| \leq C \Delta^3.
\]

Proof. From the Taylor series expansion,
\[
\ell_a(\mu_a) - \ell(\mu'_a) = \ell_a(\mu_a - \mu'_a) + \frac{1}{2} \ell''(\mu_a)(\mu_a - \mu'_a)^2 + \frac{1}{6} \ell'''(\tilde{\mu})(\mu_a - \mu'_a)^3
\] (6)
where \( \bar{\mu} \) has the value between \( \mu_a \) and \( \mu'_a \). Note that \( \mathbb{E}_{\nu'}[\ell'(\mu_a) - \ell(\mu'_a)] = -\text{KL}(\nu', \nu_a), \mathbb{E}_{\nu'}[\ell(\mu'_a)] = 0, \) and \( \mathbb{E}_{\nu'}[\ell(\mu'_a)] = -I_a(\mu'_a). \) Taking the expectation \( \mathbb{E}_{\nu'}[\cdot] \) for both sides of (6),

\[
-\text{KL}(\nu', \nu_a) = \frac{-I_a(\mu'_a)}{2} (\mu'_a - \mu_a)^2 + \frac{1}{6} \mathbb{E}_{\nu'}[\ell(\bar{\mu})](\mu'_a - \mu_a)^3.
\]

From the assumption, there exist constants \( c_1, c_2 > 0 \) such that \( I_a(\mu_a) - I(\mu'_a) \leq c_1 |\mu_a - \mu'_a| \leq c_1 \Delta \) and \( \mathbb{E}_{\nu'}[\ell(\bar{\mu})] \leq c_2. \) Therefore, we conclude the proof.

**C Proof of Lemma 2.6**

First, using \( C_\Delta^a(\nu) = \{ \nu' \in \Omega : a^*(\nu') = a, \forall a \in [K], |\mu_a - \mu'_a| \leq 2\Delta \}, \) note that we can write

\[
\text{Alt}_\Delta(\nu) = \bigcup_{a \neq 1} \{ \nu' \in \Omega : a^*(\nu') = a, \forall a \in [K], |\mu_a - \mu'_a| \leq 2\Delta \}
= \bigcup_{a \neq 1} C_\Delta^a(\nu).
\]

Then, we have

\[
\sup_{w \in W} \inf_{\nu' \in \text{Alt}_\Delta(\nu)} \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a}
= \sup_{w \in W} \min_{a \neq 1} \inf_{\nu' \in C_\Delta^a(\nu)} \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a}
= \sup_{w \in W} \min_{a \neq 1} \inf_{\nu' \in C_\Delta^a(\nu)} \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a}
= \sup_{w \in W} \min_{a \neq 1} \inf_{\nu' \in C_\Delta^a(\nu)} \left( \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a} \right)
\]

where (a) is from the fact that the sum-of-squares optimization does not attain the optimality outside of \([\mu_1, \mu_a]\). The optimal allocation for this problem is well known in the previous studies, e.g., Example 1 in Glynn and Juneja (2004):

\[
\min_{\lambda \in [\mu_a, \mu_1]} \left( \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a} \right) = \frac{(\mu_1 - \mu_a)^2}{2 \left( \frac{\sigma^2_1}{w_1} + \frac{\sigma^2_a}{w_a} \right)}.
\]

In summary,

\[
\sup_{w \in W} \inf_{\nu' \in \text{Alt}_\Delta(\nu)} \sum_{a=1}^{K} w_a \frac{(\mu_a - \mu'_a)^2}{2\sigma^2_a} = \sup_{w \in W} \min_{a \neq 1} \frac{(\mu_1 - \mu_a)^2}{2 \left( \frac{\sigma^2_1}{w_1} + \frac{\sigma^2_a}{w_a} \right)}.
\]

This concludes the proof.

**D Proof of Lemma 3.2**

When \( \min(w_1, w_a) = 0, G_k(w_1, w_a) = 0. \) Therefore, from now on we assume that \( \forall a \geq 2, \min(w_1, w_a) > 0. \) For each \( a \geq 2, \) we can write

\[
G_a(w_1, w_a) = w_1 g_a(x),
\]

where

\[
g_a(x) = \frac{(\mu_1 - \mu_a)^2}{2 (\sigma^2_1 + x \sigma^2_a)}.
\]
with \( x = w_1/w_a \). Note that \( g_a(x) \) is a strictly decreasing function mapping from \([0, \infty)\) to \((0, (\mu_1 - \mu_a)^2/(2\sigma^2_2))\) and we have
\[
\hat{g}_a(x) = -\frac{\mu_1 - \mu_a)^2 \sigma^2}{2(\sigma^2_1 + x\sigma^2_2)^2}
\]
as its differentiation. Let \( \psi_a(y) = g_a^{-1}(y) \) be the inverse function defined on \((0, (\mu_1 - \mu_a)^2/(2\sigma^2_2))\). Then,
\[
\psi_a(y) = \frac{(\mu_1 - \mu_a)^2 - 2y\sigma^2_1}{2\sigma^2_2}, \quad (9)
\]
\[
\dot{\psi}_a(y) = -\frac{2(\sigma^2_1 + \psi_a(y)\sigma^2_2)^2}{(\mu_1 - \mu_a)^2 \sigma^2_2} < 0. \quad (10)
\]
Let we define \( w_a^* = w_1^*/w_a^*(> 0) \). We have
\[
w_1^* = \frac{1}{1 + \sum_{i \geq 2}(1/\psi_i^*)}
\]
for \( a \geq 2 \), \( w_a^* = \frac{1/\psi_a^*}{1 + \sum_{i \geq 2}(1/\psi_i^*)} \).

From (7) and (8), \((\psi_2^*, \ldots, \psi_K^*)\) belongs to
\[
\arg \max_{(\psi_a)_{a \geq 2}} \frac{\min_{a \geq 2} g_a(\psi_a)}{1 + \sum_{a \geq 2}(1/\psi_a)}.
\]
Then, there exists \( y^* \in (0, (\mu_1 - \mu_2)^2/(2\sigma^2_2)) \) such that
\[
\forall a \geq 2, \quad g_a(\psi_a^*) = y^*.
\]
\( y^* \) belongs to
\[
\arg \max_{y \in (0, (\mu_1 - \mu_2)^2/(2\sigma^2_2))} G(y),
\]
where
\[
G(y) = \frac{y}{1 + \sum_{a \geq 2}(1/\psi_a(y))}.
\]

\( G(y) \) is differentiable and \( G'(y) = 0 \) is equivalent to
\[
y \left( -\sum_{a \geq 2} \frac{\dot{\psi}_a(y)}{\psi_a(y)^2} \right) = 1 + \sum_{a \geq 2} \frac{1}{\psi_a(y)}. \quad (11)
\]
Here, using (9) and (10), we get, for all \( a \geq 2 \),
\[
\frac{\dot{\psi}_a(y)}{\psi_a(y)^2} = \frac{2(\sigma^2_1 + \psi_a(y)\sigma^2_2)^2}{(\mu_1 - \mu_a)^2 \sigma^2_2} \frac{1}{\psi_a(y)^2}. \quad (12)
\]
Combining (11) and (12) together,
\[
\sum_{a \geq 2} \frac{2(\sigma^2_1 + \psi_a(y)\sigma^2_2)^2}{(\mu_1 - \mu_a)^2 \sigma^2_2} \frac{y}{\psi_a(y)^2} = 1 + \sum_{a \geq 2} \frac{1}{\psi_a(y)},
\]
\[
\iff \sum_{a \geq 2} \left( \frac{\sigma^2_1}{\sigma^2_a \psi_a(y)^2} + \frac{1}{\psi_a(y)} \right) = 1 + \sum_{a \geq 2} \frac{1}{\psi_a(y)} \quad (13)
\]
\[
\iff \sum_{a \geq 2} \frac{\sigma^2_1}{\sigma^2_a \psi_a(y)^2} = 1, \quad (14)
\]
where for (13), we used for each \( a \geq 2 \),
\[
y = \frac{(\mu_1 - \mu_a)^2}{2(\sigma^2_1 + \psi_a(y)\sigma^2_2)}. \quad (15)
\]
As $\psi_a(y)$ is a strictly decreasing function mapping from $(0, (\mu_1 - \mu_a)^2/(2\sigma_1^2))$ to $[0, \infty)$, $\frac{\sigma_1^2}{\sigma_a^2 \psi_a(y)}$ is a strictly increasing function mapping from $(0, (\mu_1 - \mu_a)^2/(2\sigma_1^2))$ to $(0, \infty)$. Equation (14) has a unique solution as the function

$$F(y) = \sum_{a \geq 2} \frac{\sigma_1^2}{\sigma_a^2 \psi_a(y)^2}$$

is strictly increasing, and

$$\lim_{y \to 0} F(y) = 0, \quad \lim_{y \to (\mu_1 - \mu_2)^2/(2\sigma_1^2)} F(y) = \infty.$$ 

This concludes the proof.

**E (ξ_t, F_t) is Martingale Difference Sequences**

**Proof.** Clearly, $E_\nu[|\xi_t|] < \infty$. For each $t \in [T]$, 

$$E_\nu[\xi_t | F_{t-1}] = \frac{1}{\sqrt{T \bar{\sigma}_a}} E_\nu \left[ \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a | F_{t-1} \right]$$

$$= \frac{1}{\sqrt{T \bar{\sigma}_a}} \left( E_\nu \left[ \mathbb{I}[A_t = 1] | F_{t-1} \right] E_\nu \left[ \left( X_{1,t} - \hat{\mu}_{1,t} \right) | F_{t-1} \right] + \mu_1 ight.$$

$$- E_\nu \left[ \mathbb{I}[A_t = a] | F_{t-1} \right] E_\nu \left[ \left( X_{a,t} - \hat{\mu}_{a,t} \right) | F_{t-1} \right] - \mu_a - \Delta_a \left. \right)$$

$$= 0.$$

\[\square\]

**F Proof of Lemma 4.4**

**Proof.** For the simplicity, let us denote $E_\nu$ by $E$ and $\bar{\sigma}$. Recall that $\hat{X}_{a,t}$ is constructed as

$$\hat{X}_{a,t} = \mathbb{I}[A_t = a] \left( \frac{X_{a,t} - \hat{\mu}_{a,t}}{w_{a,t}} \right) + \hat{\mu}_{a,t},$$

where

$$\hat{\mu}_{a,t} = \begin{cases} C_\mu & \text{if } C_\mu < \hat{\mu}_{a,t} \\ \hat{\mu}_{a,t} & \text{if } -C_\mu \leq \hat{\mu}_{a,t} \leq C_\mu \\ -C_\mu & \text{if } \hat{\mu}_{a,t} < -C_\mu. \end{cases}$$
For each $t = 1, \ldots, T$, we have
\[
\mathbb{E}\left[\exp\left(\frac{C_0 \sqrt{T} |x_{t-1}}{C_a}\right) | F_{t-1}\right]
\leq \mathbb{E}\left[\exp\left(\frac{C_0}{\sigma_{a,t}} \left| \hat{X}_{a,t} - \hat{X}_{a,t} \right| \right) | F_{t-1}\right]
\leq \mathbb{E}\left[\exp\left(\frac{C_0}{\sigma_{a,t}} \left| \hat{X}_{a,t} - \hat{X}_{a,t} + \frac{C_0 \Delta_{a,t}}{\sigma_{a,t}} \right| \right) | F_{t-1}\right]
\]
where for (a), we denote $\tilde{C}_1 = \exp \left(2C_0C_{\mu} / \sigma_a \right)$. Since $X_{a,t}$ under $\nu^a (\in P_a^{exp})$ is a sub-exponential random variable, there exists some universal constant $C > 0$ such that for all $\nu^a (\in P_a^{exp})$, for all $\lambda \geq 0$ such that $0 \leq \lambda \leq 1/C$, $\mathbb{E}_{\nu^a}[\exp(\lambda X_{a,t})] \leq \exp(C^2 \lambda^2)$ (Vershynin (2018), Proposition 2.7.1). Note that from the assumptions, $\Theta_a$ is compact, $|\mu_{a,t}| \leq C_{\mu}$, $\max\{\sigma_{a,t}^2, 1/\sigma_{a,t}^2\} \leq C_{\sigma_a}$, $|\mu_{a,t}| \leq C_{\mu}$, and $|w_{a,t}| \geq C_w$ for all $t \in \{1, \ldots, T\}$. Therefore, there exists a positive constant $C_1(C_0, C_{\sigma_a}, C_{\mu}, C_w)$ such that
\[
\mathbb{E}\left[\exp(C_0 \sqrt{T} |x_{t-1}|) | F_{t-1}\right] \leq C_1(C_0, C_{\sigma_a}, C_{\mu}, C_w).
\]
This concludes the proof.

**G Proof of Lemma 4.5**

For each $a \in [K]$, we denote $\mathbb{E}_{\nu_a}[X_{a,t}^2]$ by $\zeta_a$.

**Lemma G.1.** Under the RS-AIPW strategy, for each $a \in [K]$,
\[
\hat{\mu}_{a,t} \xrightarrow{a.s.} \mu_a,
\hat{\zeta}_{a,t} \xrightarrow{a.s.} \zeta_a.
\]

**Proof.** Under the RS-AIPW strategy, we select each arm with a positive probability (at least $C_w$) for all $t \in [T]$. This implies that with probability 1, we select each arm infinitely often as $T \to \infty$. Therefore, from the strong law of large numbers for martingales (Proposition A.4), $\hat{\mu}_{a,t} \xrightarrow{a.s.} \mu_a$ and $\hat{\zeta}_{a,t} \xrightarrow{a.s.} \zeta_a$. □

This lemma and the continuity of $w^*$ with respect to $\mu_a$ and $\sigma_a$ (see Lemma 3.2) directly implies the following corollary, which states the almost sure convergence of $w_{a,t}$.

**Corollary G.2.** Under the RS-AIPW strategy, for each $a \in [K]$,
\[
w_{a,t} \xrightarrow{a.s.} w^*_a.
\]

Then, we present the following results on the convergence of the second moment.

**Lemma G.3.** Recall we define for each $a \in [K] \setminus \{1\}$,
\[
\hat{\sigma}_a = \sqrt{\frac{\sigma_1^2}{w_1^2} + \frac{\sigma_2^2}{w_2^2}}
\]
Under the RS-AIPW strategy, for each \( a \in [K] \setminus \{1\} \), with probability 1,

\[
\lim_{t \to \infty} \mathbb{E}_{\nu} \left( \mathbb{E}_{\nu} \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 \big| \mathcal{F}_{t-1} \right] - \hat{\sigma}_a^2 \right) = 0.
\]

**Proof.**

\[
\begin{align*}
\mathbb{E}_{\nu} \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 \big| \mathcal{F}_{t-1} \right] &= \mathbb{E}_{\nu} \left[ \left( \frac{1[A_t = 1]}{w_{1,t}} (X_{1,t} - \hat{\mu}_{1,t}) - \frac{1[A_t = a]}{w_{a,t}} (X_{a,t} - \hat{\mu}_{a,t}) + \hat{\mu}_{1,t} - \hat{\mu}_{a,t} - \Delta_a \right)^2 \big| \mathcal{F}_{t-1} \right] \\
&= \mathbb{E}_{\nu} \left[ \left( \frac{1[A_t = 1]}{w_{1,t}} (X_{1,t} - \hat{\mu}_{1,t}) - \frac{1[A_t = a]}{w_{a,t}} (X_{a,t} - \hat{\mu}_{a,t}) \right)^2 \big| \mathcal{F}_{t-1} \right] \\
&\quad + 2 \left( \frac{1[A_t = 1]}{w_{1,t}} (X_{1,t} - \hat{\mu}_{1,t}) - \frac{1[A_t = a]}{w_{a,t}} (X_{a,t} - \hat{\mu}_{a,t}) \right) (\hat{\mu}_{1,t} - \hat{\mu}_{a,t} - \Delta_a) \\
&\quad + (\hat{\mu}_{1,t} - \hat{\mu}_{a,t} - \Delta_a)^2 \mathbb{E}_{\nu}\left[ \big| \mathcal{F}_{t-1} \right] \\
&= \mathbb{E}_{\nu} \left[ \frac{(X_{1,t} - \hat{\mu}_{1,t})^2}{w_{1,t}} \big| \mathcal{F}_{t-1} \right] + \mathbb{E}_{\nu} \left[ \frac{(X_{a,t} - \hat{\mu}_{a,t})^2}{w_{a,t}} \big| \mathcal{F}_{t-1} \right] - (\hat{\mu}_{1,t} + \hat{\mu}_{a,t} - \Delta_a)^2.
\end{align*}
\]

Here, we used

\[
\mathbb{E}_{\nu} \left[ \frac{1[A_t = a]}{w_{a,t}} (X_{a,t} - \hat{\mu}_{a,t})^2 \big| \mathcal{F}_{t-1} \right] = \mathbb{E}_{\nu} \left[ \frac{w_{a,t} (X_{a,t} - \hat{\mu}_{a,t})^2}{w_{a,t}^2} \big| \mathcal{F}_{t-1} \right] = \mathbb{E}_{\nu} \left[ \frac{(X_{a,t} - \hat{\mu}_{a,t})^2}{w_{a,t}} \big| \mathcal{F}_{t-1} \right]
\]

and

\[
\mathbb{E}_{\nu} \left[ \frac{1[A_t = 1]}{w_{1,t}} (X_{1,t} - \hat{\mu}_{1,t}) (\hat{\mu}_{1,t} - \hat{\mu}_{a,t} - \Delta_a) \big| \mathcal{F}_{t-1} \right] = (\hat{\mu}_{1,t} - \hat{\mu}_{a,t} - \Delta_a) \mathbb{E}_{\nu} \left[ \frac{w_{1,t} (X_{1,t} - \hat{\mu}_{1,t})}{w_{1,t}} \big| \mathcal{F}_{t-1} \right].
\]

We also have

\[
\mathbb{E}_{\nu} \left[ \frac{(X_{a,t} - \hat{\mu}_{a,t})^2}{w_{a,t}} \big| \mathcal{F}_{t-1} \right] = \mathbb{E}_{\nu} \left[ X_{a,t}^2 \right] - 2 \mu_a \hat{\mu}_{a,t} + \hat{\mu}_{a,t}^2 = \mathbb{E}_{\nu} \left[ X_{a,t}^2 \right] - \mu_a^2 + (\mu_a - \hat{\mu}_{a,t})^2.
\]

Then,

\[
\begin{align*}
\mathbb{E}_{\nu} \left[ \frac{(X_{1,t} - \hat{\mu}_{1,t})^2}{w_{1,t}} \big| \mathcal{F}_{t-1} \right] + \mathbb{E}_{\nu} \left[ \frac{(X_{a,t} - \hat{\mu}_{a,t})^2}{w_{a,t}} \big| \mathcal{F}_{t-1} \right] - (\hat{\mu}_{1,t} + \hat{\mu}_{a,t} - \Delta_a)^2 \\
= \mathbb{E}_{\nu} \left[ X_{1,t}^2 \right] - \mu_1^2 + (\mu_1 - \hat{\mu}_{1,t})^2 + \mathbb{E}_{\nu} \left[ X_{a,t}^2 \right] - \mu_a^2 + (\mu_a - \hat{\mu}_{a,t})^2 - (\hat{\mu}_{1,t} + \hat{\mu}_{a,t} - \Delta_a)^2.
\end{align*}
\]
Because $\mu_{a,t} \xrightarrow{a.s.} \mu_a$ and $w_{a,t} \xrightarrow{a.s.} w_a^*$, with probability 1,

$$
\lim_{t \to \infty} \left| \frac{E_\nu [X_{1,t}^2] - \mu_a^2 + (\mu_1 - \hat{\mu}_{1,t})^2}{w_{1,t}} \right| + \left| \frac{E_\nu [X_{a,t}^2] - \mu_a^2 + (\mu_a - \hat{\mu}_{a,t})^2}{w_{a,t}} \right|
- (\hat{\mu}_{1,t} + \hat{\mu}_{a,t} - \Delta_a)^2 - \sigma_1^2 - \frac{\sigma_a^2}{w_a^*}
\leq \lim_{t \to \infty} \frac{E_\nu [X_{1,t}^2] - \mu_a^2}{w_{1,t}} - \frac{\sigma_1^2}{w_1^*} + \lim_{t \to \infty} \frac{E_\nu [X_{a,t}^2] - \mu_a^2}{w_{a,t}} - \frac{\sigma_a^2}{w_a^*}
+ \lim_{t \to \infty} \frac{(\mu_1 - \hat{\mu}_{1,t})^2}{w_{1,t}} + \lim_{t \to \infty} \frac{(\mu_a - \hat{\mu}_{a,t})^2}{w_{a,t}} + \lim_{t \to \infty} (\hat{\mu}_{1,t} + \hat{\mu}_{a,t} - \Delta_a)^2
= 0.
$$

Note that $E_\nu [X_{a,t}^2] - \mu_a^2 = \sigma_a^2$. This directly implies that

$$
\frac{1}{T} \sum_{t=1}^T E_\nu \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 | F_{t-1} \right] - \left( \frac{\sigma_1^2}{w_1^*} + \frac{\sigma_a^2}{w_a^*} \right) \xrightarrow{a.s.} 0,
$$

$$
\iff \frac{1}{T} \sum_{t=1}^T E_\nu \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 | F_{t-1} \right] - 1 \xrightarrow{a.s.} 0,
$$

Because $X_{a,t}$ is a sub-exponential random variable, and the other variables in $\hat{X}_{1,t}$ and $\hat{X}_{a,t}$ are bounded,

$$
\frac{1}{T} \sum_{t=1}^T E_\nu \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 | F_{t-1} \right] - 1
$$

is uniformly integrable from Proposition A.2. Then, from Proposition A.3, for any $\delta$, there exists $T_0$ such that for all $T > T_0$

$$
E_\nu \left[ \left| \frac{1}{T} \sum_{t=1}^T E_\nu \left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta_a \right)^2 | F_{t-1} \right] - 1 \right| \leq \delta.\right.
$$

This concludes the proof.

\[\square\]

### H Proof of Theorem 4.2: Large Deviation Bound for Martingales

For brevity, let us denote $P_\nu$ and $E_\nu$ by $P$ and $E$, respectively. For all $t = 1, \ldots, T$, let us define

$$
r_t(\lambda) = \frac{\exp (\lambda \xi_t)}{\mathbb{E} [\exp (\lambda \xi_t)]},
$$

and

$$
\eta_t(\lambda) = \xi_t - b_t(\lambda),
$$

where

$$
b_t(\lambda) = E[r_t(\lambda) \xi_t].
$$

Then, we obtain the following decomposition:

$$
Z_T = U_T(\lambda) + B_T(\lambda),
$$

where

$$
U_T(\lambda) = \sum_{t=1}^T \eta_t(\lambda)
$$

and

$$
B_T(\lambda) = \sum_{t=1}^T b_t(\lambda).
$$

Let $Psi_T(\lambda) = \sum_{t=1}^T \log \mathbb{E} [\exp (\lambda \xi_t)].$
Lemma H.1. Under Condition A,
\[
\mathbb{E} \left[ |\xi_t|^k \mid \mathcal{F}_{t-1} \right] \leq k! \left( C_0 T^{1/2} \right)^{-k} C_1, \quad \text{for all } k \geq 2.
\]

Proof. Applying the elementary inequality \( x^k/k! \leq \exp(x), \forall x \geq 0, \) to \( x = C_0 \sqrt{T} |\xi_t|, \) for \( k \geq 2, \)
\[
|\xi_t|^k \leq k! (C_0 T^{1/2})^{-k} \exp(C_0 \sqrt{T} |\xi_t|).
\]
Taking expectations on both sides, with Condition A, we obtain the desired inequality. Recall that Condition A is
\[
\text{for some positive constants } C_0 \text{ and } C_1.
\]

\[\square\]

Lemma H.2. Under Condition A, there exists some constant \( C > 0 \) such that for all \( 0 \leq \lambda \leq \frac{1}{4} C_0 \sqrt{T}, \)
\[
|B_T(\lambda) - \lambda| \leq C \left( \lambda V_T + \lambda^2 / \sqrt{T} \right).
\]

Proof. By definition, for \( t = 1, \ldots, T, \)
\[
b_t(\lambda) = \frac{\mathbb{E} \left[ \xi_t \exp(\lambda \xi_t) \right]}{\mathbb{E} \left[ \exp(\lambda \xi_t) \right]}.
\]
Jensen’s inequality and \( \mathbb{E}[\xi_t] = \mathbb{E}[\mathbb{E}[\xi_t | \mathcal{F}_{t-1}]] = 0 \) implies that \( \mathbb{E}[\exp(\lambda \xi_t)] \geq 1 \) and
\[
\mathbb{E} [\xi_t \exp(\lambda \xi_t)] = \mathbb{E} [\xi_t (\exp(\lambda \xi_t) - 1)] \geq 0, \quad \text{for } \lambda \geq 0.
\]
We find that
\[
B_T(\lambda) \leq \sum_{t=1}^{T} \mathbb{E} [\xi_t \exp(\lambda \xi_t)]
\]
\[
= \lambda \mathbb{E}[W_T] + \sum_{t=1}^{T} \sum_{k=2}^{\infty} \mathbb{E} \left[ \frac{\xi_t (\lambda \xi_t)^k}{k!} \right],
\]
by the Taylor series expansion for \( \exp(x). \) Here, using Lemma H.1 and \( \mathbb{E} \left[ \xi_t^{k+1} \right] = \mathbb{E} \left[ \mathbb{E} \left[ \xi_t^{k+1} | \mathcal{F}_{t-1} \right] \right], \) for some constant \( C_2, \)
\[
\sum_{t=1}^{T} \sum_{k=2}^{\infty} \mathbb{E} \left[ \frac{\xi_t (\lambda \xi_t)^k}{k!} \right] \leq \sum_{t=1}^{T} \sum_{k=2}^{\infty} \mathbb{E} \left[ \xi_t^{k+1} \right] \frac{\lambda^k}{k!}
\]
\[
\leq \sum_{t=1}^{T} \sum_{k=2}^{\infty} (k + 1)! \left( C_0 T^{1/2} \right)^{-(k+1)} C_1 \frac{\lambda^k}{k!}
\]
\[
\leq C_2 \lambda^2 / \sqrt{T}.
\]
Therefore,
\[
B_T(\lambda) \leq \lambda + \lambda V_T + C_2 \lambda^2 / \sqrt{T}.
\]
Next, we show the lower bound of \( B_T(\lambda). \) First, by using Lemma H.1, using some constant \( C_3 > 0, \) for all \( 0 \leq \lambda \leq \frac{1}{4} C_0 \sqrt{T}, \)
\[
\mathbb{E} \left[ \exp(\lambda \xi_t) \right] \leq 1 + \sum_{k=2}^{\infty} \mathbb{E} \left[ \frac{(\lambda \xi_t)^k}{k!} \right]
\]
\[
\leq 1 + C_1 \sum_{k=2}^{\infty} \lambda^k (C_0 \sqrt{T})^{-k}
\]
\[
\leq 1 + C_3 \lambda^2 T^{-1}.
\]
This inequality together with (15) implies the lower bound of $B_T(\lambda)$: for some positive constant $C_4$,

$$B_T(\lambda) = \sum_{t=1}^{T} \frac{\mathbb{E}[\xi_t \exp(\lambda \xi_t)]}{\mathbb{E}[\exp(\lambda \xi_t)]} \geq \left( \sum_{t=1}^{T} \mathbb{E}[\xi_t \exp(\lambda \xi_t)] \right) (1 + C_3 \lambda^2 T^{-1})^{-1}$$

$$= \left( \lambda W_T + \sum_{t=1}^{T} \sum_{k=2}^{\infty} \mathbb{E} \left[ \frac{\xi_t (\lambda \xi_t)^k}{k!} \right] \right) (1 + C_3 \lambda^2 T^{-1})^{-1}$$

$$\geq \left( \lambda W_T - \sum_{t=1}^{T} \sum_{k=2}^{\infty} \mathbb{E} \left[ \frac{\xi_t (\lambda \xi_t)^k}{k!} \right] \right) (1 + C_3 \lambda^2 T^{-1})^{-1}$$

$$\geq (\lambda - \lambda V_T - C_2 \lambda^2 / \sqrt{T}) (1 + C_3 \lambda^2 T^{-1})^{-1}$$

$$\geq \lambda - \lambda V_T - C_4 \lambda^2 / \sqrt{T}.$$ This concludes the proof.

**Lemma H.3.** Assume Condition A, there exists some constant $C > 0$ such that for all $0 \leq \lambda \leq \frac{1}{4} C_0 \sqrt{T}$,

$$\left| \Psi_T(\lambda) - \frac{\lambda^2}{2} \right| \leq C \left( \lambda^3 / \sqrt{T} + \lambda^2 V_T \right).$$

**Proof.** First, we have $\mathbb{E}[\exp(\lambda \xi_t)] \geq 1$ from Jensen’s inequality. Using a two-term Taylor’s expansion of $\log(1 + \varphi)$, $\varphi \geq 0$, there exists $0 \leq \varphi_t^* \leq \mathbb{E}[\exp(\lambda \xi_t)] - 1$ (for $t = 1, \ldots, T$) such that

$$\Psi_T(\lambda) = \log \prod_{t=1}^{T} \mathbb{E}[\exp(\lambda \xi_t)]$$

$$= \sum_{t=1}^{T} \left( (\mathbb{E}[\exp(\lambda \xi_t)] - 1) - \frac{1}{2} \left( \frac{1}{1 + \varphi_t^*} \right)^2 (\mathbb{E}[\exp(\lambda \xi_t)] - 1)^2 \right).$$

Because $(\xi_t)$ is a martingale difference sequence, $\mathbb{E}[\xi_t] = \mathbb{E}[\mathbb{E}[\xi_t | \mathcal{F}_{t-1}]] = 0$. Therefore,

$$\Psi_T(\lambda) - \frac{\lambda^2}{2} \mathbb{E}[W_T]$$

$$= \sum_{t=1}^{T} \left( (\mathbb{E}[\exp(\lambda \xi_t)] - 1) - \frac{1}{2} \left( \frac{1}{1 + \varphi_t^*} \right)^2 (\mathbb{E}[\exp(\lambda \xi_t)] - 1)^2 \right) - \sum_{t=1}^{T} \left( \lambda \mathbb{E}[\xi_t] + \frac{\lambda^2}{2} \mathbb{E}[\xi_t^2] \right)$$

Then, by using $\mathbb{E}[\exp(\lambda \xi_t)] \geq 1$, we have

$$\left| \Psi_T(\lambda) - \frac{\lambda^2}{2} \mathbb{E}[W_T] \right| \leq \sum_{t=1}^{T} \left| \mathbb{E}[\exp(\lambda \xi_t)] - 1 - \lambda \mathbb{E}[\xi_t] - \frac{\lambda^2}{2} \mathbb{E}[\xi_t^2] \right| + \frac{1}{2} \sum_{t=1}^{T} (\mathbb{E}[\exp(\lambda \xi_t)] - 1)^2$$

$$\leq \sum_{t=1}^{T} \sum_{k=3}^{\infty} \frac{\lambda^k}{k!} \mathbb{E} \left[ \xi_t^k \right] + \frac{1}{2} \sum_{t=1}^{T} \left( \sum_{k=3}^{\infty} \frac{\lambda^k}{k!} \mathbb{E} \left[ \xi_t^k \right] \right)^2.$$

From Lemma H.1, for a constant $C_3$,

$$\left| \Psi_T(\lambda) - \frac{\lambda^2}{2} \mathbb{E}[W_T] \right| \leq C_3 \lambda^3 / \sqrt{T}$$

In conclusion, we have

$$\left| \Psi_T(\lambda) - \frac{\lambda^2}{2} \right| \leq C_3 \lambda^3 / \sqrt{T} + \frac{\lambda^2}{2} (\mathbb{E}[W_T - 1]) \leq C_3 \lambda^3 / \sqrt{T} + \frac{\lambda^2}{2} (||W_T - 1||).$$
Recall that $V_T = \mathbb{E}[|W_T - 1|]$. Then,

$$\left| \Psi_T(\lambda) - \frac{\lambda^2}{2} \right| \leq C \left( \lambda^3 / \sqrt{T} + \lambda^2 V_T \right).$$

By using Lemmas H.1–H.3, we show the proof of Theorem 4.2.

**Proof of Theorem 4.2.** There exists some constant $C > 0$ such that for all $1 \leq u \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_0^2}{8C_1}} \right\}$,

$$\mathbb{P}(Z_T > u)$$

$$= \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right)^{-1} \mathbb{1}[Z_T > u] d\mathbb{P}$$

$$= \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \exp \left( -\lambda \sum_{t=1}^{T} \xi_t + \log \left( \prod_{t=1}^{T} \mathbb{E}[\exp(\lambda \xi_t)] \right) \right) \mathbb{1}[Z_T > u] d\mathbb{P}$$

$$= \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \exp \left( -\lambda Z_T + \Psi_T(\lambda) \right) \mathbb{1}[Z_T > u] d\mathbb{P}$$

$$= \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \exp \left( -\lambda U_T(\lambda) - \lambda B_T(\lambda) + \Psi_T(\lambda) \right) \mathbb{1}[U_T(\lambda) + B_T(\lambda) > u] d\mathbb{P},$$

$$\leq \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \exp \left( -\lambda U_T(\lambda) - \frac{\lambda^2}{2} + C(\lambda^3 / \sqrt{T} + \lambda^2 V_T) \right)$$

$$\cdot \mathbb{1}\left[U_T(\lambda) + \lambda + C(\lambda V_T + \lambda^2 / \sqrt{T}) > u\right] d\mathbb{P},$$

where for the last inequality, we used Lemma H.2 and Lemma H.3. Let $\lambda = \lambda(u)$ be the largest solution of the equation

$$\lambda + C(\lambda V_T + \lambda^2 / \sqrt{T}) = u.$$

The definition of $\lambda$ implies that there exist $C' > 0$ such that, for all $1 \leq u \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_0^2}{8C_1}} \right\}$,

$$C'u \leq \lambda(u) = \frac{2u}{\sqrt{(1 + CV_T)^2 + 4Cu/\sqrt{T} + CV_T} + 1} \leq u \quad \text{(16)}$$

and there exists $\theta \in (0, 1]$ such that

$$\lambda(u) = u - C(\lambda V_T + \lambda^2 / \sqrt{T})$$

$$= u - C\theta(u V_T + u^2 / \sqrt{T}) \in \left[C', \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_0^2}{8C_1}} \right\} \right]. \quad \text{(17)}$$

Then, we obtain for all $1 \leq u \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C_0^2}{8C_1}} \right\}$,

$$\mathbb{P}(Z_T > u)$$

$$\leq \exp \left( C \left( \lambda^3 T^{-1/2} + \lambda^2 V_T \right) - \frac{\lambda^2}{2} \right) \int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]} \right) \exp \left( -\lambda U_T(\lambda) \right) \mathbb{1}[U_T(\lambda) > 0] d\mathbb{P}. $$
Here, we have
\[
\int \left( \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]]} \right) \exp(-\mathcal{X}U_T(\mathcal{X})) \mathbb{1}[U_T(\mathcal{X}) > 0] d\mathbb{P} = \mathbb{E} \left[ \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]]} \right] \exp(-\mathcal{X}U_T(\mathcal{X})) \mathbb{1}[U_T(\mathcal{X}) > 0].
\]

We also define another measure $\tilde{\mathbb{P}}_\lambda$ as
\[
d\tilde{\mathbb{P}}_\lambda = \frac{\prod_{t=1}^{T} \exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]} d\mathbb{P} = \frac{\exp(\lambda \sum_{t=1}^{T} \xi_t)}{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]} d\mathbb{P}.
\]

Note that $\tilde{\mathbb{P}}_\lambda$ is a probability measure, as the following holds
\[
\int d\tilde{\mathbb{P}}_\lambda = \int \frac{\exp(\lambda \sum_{t=1}^{T} \xi_t)}{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]} d\mathbb{P} = \frac{1}{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]} \int \exp(\lambda \sum_{t=1}^{T} \xi_t) d\mathbb{P} = \frac{1}{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]} \cdot \mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)] = 1.
\]

We further denote $\tilde{\mathbb{E}}_\lambda$ as the expectation under the measure $\tilde{\mathbb{P}}_\lambda$. In the same way as (37) and (38) in Fan et al. (2013), it is easy to see that
\[
\mathbb{E} \left[ \prod_{t=1}^{T} \frac{\exp(\lambda \xi_t)}{\mathbb{E}[\exp(\lambda \xi_t)]]} \right] \exp(-\mathcal{X}U_T(\mathcal{X})) \mathbb{1}[U_T(\mathcal{X}) > 0] = \frac{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]}{\prod_{t=1}^{T} \mathbb{E}[\exp(\lambda \xi_t)]]} \sum_{t=1}^{T} \mathbb{E}[\exp(-\mathcal{X}U_T(\mathcal{X})) \mathbb{1}[U_T(\mathcal{X}) > 0]]
\]
\[
= \frac{\mathbb{E}[\exp(\lambda \sum_{t=1}^{T} \xi_t)]]}{\prod_{t=1}^{T} \mathbb{E}[\exp(\lambda \xi_t)]]} \int_{0}^{\infty} \tilde{\mathbb{E}}_{\lambda}(\mathcal{X}) \exp(-\mathcal{X}y)dy(0 < U_T(\mathcal{X}) < y), \tag{18}
\]
and for a standard Gaussian random variable $\mathcal{N}$,
\[
\mathbb{E}[\exp(-\mathcal{X} \mathcal{N}) \mathbb{1}[\mathcal{N} > 0]] = \int_{0}^{\infty} \tilde{\mathbb{E}}_{\lambda}(\mathcal{X}) \exp(-\mathcal{X}y)dy(0 < \mathcal{N} < y). \tag{19}
\]

From (18) and (19),
\[
\left| \mathbb{E}(\tilde{\mathbb{E}}_{\lambda}(\mathcal{X}) \mathbb{1}[U_T(\mathcal{X}) > 0]) - \mathbb{E}[\exp(-\mathcal{X} \mathcal{N}) \mathbb{1}[\mathcal{N} > 0]] \right| \leq 2 \sup_{g} \left| \tilde{\mathbb{E}}_{\lambda}(U_T(\mathcal{X}) \leq g) - \Phi(g) \right|
\]
Therefore,

$$\mathbb{P}(Z_T > u) \leq \mathbb{E} \left[ \exp \left( \sum_{t=1}^{T} \lambda \xi_t \right) \right] \mathbb{E} \left[ \exp \left( C \left( \frac{\lambda^2}{\sqrt{T}} + \lambda^2 V_T \right) - \lambda^2 / 2 \right) \right] \mathbb{E} \left[ \exp \left( -\lambda U_T(\lambda) \right) \mathbb{1}[U_T(\lambda) > 0] \right]$$

$$\leq \mathbb{E} \left[ \frac{\exp \left( \sum_{t=1}^{T} \lambda \xi_t \right)}{\prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) \right]} \right] \mathbb{E} \left[ \exp \left( C \left( \frac{\lambda^2}{\sqrt{T}} + \lambda^2 V_T \right) - \lambda^2 / 2 \right) \right] \times \left( \mathbb{E} \left[ \exp \left( -\lambda N \right) \mathbb{1}[N > 0] \right] + 2 \sup_g \mathbb{E} \left[ U_T(\lambda) \leq g \right] - \Phi(g) \right)$$

$$\leq \mathbb{E} \left[ \frac{\exp \left( \sum_{t=1}^{T} \lambda \xi_t \right)}{\prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) \right]} \right] \mathbb{E} \left[ \exp \left( C \left( \frac{\lambda^2}{\sqrt{T}} + \lambda^2 V_T \right) - \lambda^2 / 2 \right) \right] \left( \mathbb{E} \left[ \exp \left( -\lambda N \right) \mathbb{1}[N > 0] \right] + 2 \right).$$

Here,

$$\exp \left( -\lambda^2 / 2 \right) \mathbb{E} \left[ \exp \left( -\lambda N \right) \mathbb{1}[N > 0] \right] = \frac{1}{\sqrt{2\pi}} \int_{0}^{\infty} \exp \left( -(y - \lambda)^2 \right) dy = 1 - \Phi(\lambda).$$

From (41) of Fan et al. (2013), for all \(\lambda \geq C'\), we have

$$1 - \Phi(\lambda) \geq \frac{C'}{2\pi(1 + C')} \frac{1}{\lambda} \exp \left( -\frac{\lambda^2}{2} \right).$$

Therefore, with some constant \(\bar{C}\), for all \(1 \leq u \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3C}{8C'}} \right\},

$$\mathbb{P}(Z_T > u) \leq \mathbb{E} \left[ \frac{\exp \left( \sum_{t=1}^{T} \lambda \xi_t \right)}{\prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) \right]} \right] \left\{ \left( 1 - \Phi(\lambda) \right) + \lambda \left( 1 - \Phi(\lambda) \right) c \right\} \mathbb{E} \left[ \exp \left( C \left( \frac{\lambda^2}{\sqrt{T}} + \lambda^2 V_T \right) \right) \right] \leq \mathbb{E} \left[ \frac{\exp \left( \sum_{t=1}^{T} \lambda \xi_t \right)}{\prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) \right]} \right] \bar{C} \lambda \left( 1 - \Phi(\lambda) \right) \mathbb{E} \left[ \exp \left( C \left( \frac{\lambda^2}{\sqrt{T}} + \lambda^2 V_T \right) \right) \right],$$

$$\text{(20)}$$

where \(c = \sqrt{2\pi(1 + C')/C'}\), and \(\bar{C}\) is chosen to be \(\bar{C} \lambda \geq (1 + \lambda \phi)\) (Note that \(\lambda \geq C'\) from (16)). Now, we consider bounding the term

$$\mathbb{E} \left[ \frac{\exp \left( \sum_{t=1}^{T} \lambda \xi_t \right)}{\prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) \right]} \right].$$

Here, we have

$$\mathbb{E} \left[ \exp \left( \sum_{t=1}^{T} \lambda \xi_t \right) \right] = \mathbb{E} \left[ \prod_{t=1}^{T} \mathbb{E} \left[ \exp (\lambda \xi_t) | F_{t-1} \right] \right].$$

Then, by using Lemma H.1, for each \(t = 1, \ldots, T,\)

$$\mathbb{E} \left[ \exp (\lambda \xi_t) | F_{t-1} \right] \leq 1 + \frac{\lambda^2}{2} \mathbb{E} \left[ \xi_t^2 | F_{t-1} \right] + \sum_{k=3}^{\infty} \frac{\lambda^k}{k!} \mathbb{E} \left[ \xi_t^k | F_{t-1} \right]$$

$$\leq 1 + \frac{\lambda^2}{2} \mathbb{E} \left[ \xi_t^2 | F_{t-1} \right] + \sum_{k=3}^{\infty} \lambda^k C_1 (C_0 \sqrt{T})^{-k}$$

$$\leq 1 + \frac{\lambda^2}{2} \mathbb{E} \left[ \xi_t^2 | F_{t-1} \right] + O \left( \lambda^3 / T^{3/2} \right).$$
Therefore,

\[
E \left[ \exp \left( \lambda \sum_{t=1}^{T} \xi_t \right) \right] \leq E \left[ \prod_{t=1}^{T} \left( 1 + \frac{\lambda}{2} E \left[ \xi_t^2 | F_{t-1} \right] + O \left( \lambda^3 / T^{3/2} \right) \right) \right] \\
\leq E \left[ \prod_{t=1}^{T} \exp \left( \frac{\lambda}{2} E \left[ \xi_t^2 | F_{t-1} \right] + O \left( \lambda^3 / T^{3/2} \right) \right) \right].
\]

Similarly, by using Lemma H.1 and constants \( c, \tilde{c} > 0 \), we have

\[
E \left[ \exp \left( \lambda \hat{\xi}_t \right) \right] = \exp \left( \log E \left[ \exp \left( \lambda \hat{\xi}_t \right) \right] \right) = \exp \left( \log \left( 1 + \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right) \right)
\]

\[
= \exp \left( \frac{\lambda^2}{2} E \left[ \xi_t^2 \right] + \sum_{k=3}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right) - \frac{1}{2} \left( \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right)^2 + \frac{1}{3} \left( \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right)^3 + \ldots
\]

\[
\geq \exp \left( \frac{\lambda^2}{2} E \left[ \xi_t^2 \right] - c \sqrt{3 / T^{3/2}} \left( 4 C_1 \sqrt{T} \right)^2 - 1 \left( \frac{4 C_1 \sqrt{T}}{3 C_0 \sqrt{T}} \right)^3 - 1 \left( \frac{4 C_1 \sqrt{T}}{3 C_0 \sqrt{T}} \right)^4 - \ldots \right)
\]

\[
\geq \exp \left( \frac{\lambda^2}{2} E \left[ \xi_t^2 \right] - c \sqrt{3 / T^{3/2}} - \left( 4 C_1 \sqrt{T} \right)^2 - \left( \frac{4 C_1 \sqrt{T}}{3 C_0 \sqrt{T}} \right) - \left( \frac{4 C_1 \sqrt{T}}{3 C_0 \sqrt{T}} \right)^3 - \left( \frac{4 C_1 \sqrt{T}}{3 C_0 \sqrt{T}} \right)^4 \right)
\]

\[
\geq \exp \left( \frac{\lambda^2}{2} E \left[ \xi_t^2 \right] - c \sqrt{3 / T} - c \lambda^4 / T^2 \right).
\]

For (a), we used Jensen’s inequality for \( m = 2, 3, \ldots \) as

\[
-(-1)^m \frac{1}{m} \left( \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right)^m \geq - \frac{1}{m} \left( \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right)^m \geq - \frac{1}{m} \left( \sum_{k=2}^{\infty} E \left[ \frac{\lambda \hat{\xi}_t}{k!} \right] \right)^m.
\]

For (b), we used the fact there exist a constant \( c > 0 \) such that

\[
E \left[ \sum_{k=2}^{\infty} \frac{\lambda \hat{\xi}_t}{k!} \right] = \sum_{k=2}^{\infty} \frac{\lambda \hat{\xi}_t}{k!} \cdot k! \lambda^k / (C_0 \sqrt{T})^k
\]

\[
= C_1 \lambda^2 \left( \frac{\lambda}{C_0 \sqrt{T}} \right)^k
\]

\[
= C_1 \lambda^2 \left( \frac{1}{C_0 \sqrt{T}} - \frac{\lambda}{C_0 \sqrt{T}} \right)^k
\]

\[
\leq C_1 \lambda^2 \left( \frac{1}{C_0 \sqrt{T}} \right)^k
\]

\[
= C_1 \lambda^2 \left( \frac{3 C_0 \sqrt{T}}{3 C_0 \sqrt{T}} \right)^k
\]

\[
\leq \frac{1}{2}.
\]
and

$$\mathbb{E}\left[ \sum_{k=3}^{\infty} \frac{|\bar{X}_t|^k}{k!} \right] \leq \frac{1}{(C_0 \sqrt{T})^k} \mathbb{E}\left[ \sum_{k=3}^{\infty} \frac{\bar{X}^k}{k!} \right] \leq c \left( \frac{\bar{X}}{\sqrt{T}} \right)^3,$$

for (c), we used Lemma H.1, and for (d), we used (16). Then, by combining the above upper and lower bounds, with some constant $\bar{C}_0, \bar{C}_1 > 0$,

$$\mathbb{E}\left[ \exp \left( \sum_{t=1}^{T} \xi_t \right) \right] \leq \mathbb{E}\left[ \prod_{t=1}^{T} \exp \left( \frac{\bar{X}}{2} + O \left( \frac{\bar{X}^2}{T} \right) \right) \right]$$

$$= \exp \left( \bar{C}_0 \bar{X}^4 / T + \bar{C}_1 \bar{X}^3 / \sqrt{T} \right) \mathbb{E}\left[ \prod_{t=1}^{T} \exp \left( \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] / 2 \right) \right) \right].$$

Using Hölder’s inequality,

$$\mathbb{E}\left[ \exp \left( \sum_{t=1}^{T} \xi_t \right) \right] \leq \exp \left( \bar{C}_0 \bar{X}^4 / T + \bar{C}_1 \bar{X}^3 / \sqrt{T} \right) \mathbb{E}\left[ \prod_{t=1}^{T} \exp \left( \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] / 2 \right) \right) \right]$$

$$\leq \exp \left( \bar{C}_0 \bar{X}^4 / T + \bar{C}_1 \bar{X}^3 / \sqrt{T} \right) \prod_{t=1}^{T} \left( \mathbb{E}\left[ \exp \left( \bar{T} \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right) / 2 \right) \right) \right)^{\frac{1}{2}}$$

$$\leq \exp \left( \bar{C}_0 \bar{X}^4 / T + \bar{C}_1 \bar{X}^3 / \sqrt{T} \right) \prod_{t=1}^{T} \left( \mathbb{E}\left[ \exp \left( \bar{T} \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right) \right) \right) \right)^{\frac{1}{2}}, \quad (21)$$

where the last inequality is from Jensen’s inequality. Note that the term

$$\bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right)$$

is bounded by some constant because $w_{a,t}$ and $\mu_{a,t}$ are bounded and $\bar{X} \leq \sqrt{T} \min \left\{ \frac{1}{4} C_0, \sqrt{\frac{3 \bar{C}_0}{8 \bar{C}_1}} \right\}$. Then,

$$\left| \mathbb{E}\left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta \right)^2 | F_{t-1} \right] - \mathbb{E}\left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta \right)^2 \right] \right|$$

$$\leq \left| \mathbb{E}\left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta \right)^2 | F_{t-1} \right] - \left( \frac{\sigma_t^2}{w_{t1}^2} + \frac{\sigma_a^2}{w_{a}^2} \right) \right| + \left| \mathbb{E}\left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta \right)^2 \right] - \left( \frac{\sigma_t^2}{w_{t1}^2} + \frac{\sigma_a^2}{w_{a}^2} \right) \right|$$

$$= \left| \mathbb{E}\left[ \left( \hat{X}_{1,t} - \hat{X}_{a,t} - \Delta \right)^2 | F_{t-1} \right] - \left( \frac{\sigma_t^2}{w_{t1}^2} + \frac{\sigma_a^2}{w_{a}^2} \right) \right|$$

$$= o_p(1),$$

where the last equality is from Lemma G.3 and the asymptotic notation $o_p(\cdot)$ is as $t \to \infty$. This implies

$$\exp \left( \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right) \right) = o_p(1).$$

By Proposition A.2 (a), the sequence

$$\left\{ \exp \left( \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right) \right) \right\}_{t \geq 1}$$

is uniformly integrable. From $L^p$-convergence theorem (Proposition A.3),

$$\mathbb{E}\left[ \exp \left( \bar{X}^2 \left( \mathbb{E}[\xi_t^4 | F_{t-1}] - \mathbb{E}[\xi_t^2] \right) \right) \right] = o(1).$$
Therefore,
\[
\prod_{t=1}^{T} \left( \mathbb{E} \left[ \exp \left( \lambda^2 \left( \mathbb{E}[\xi_t^2|\mathcal{F}_{t-1}] - \mathbb{E}[\xi_t^2] \right) \right) \right] \right)^{1/2} = o(1). \tag{22}
\]

Using (21) and (22), we get, with some constants \(\hat{C}_2, \hat{C}_3 > 0\),
\[
\mathbb{E} \left[ \exp \left( \lambda \sum_{t=1}^{T} \xi_t \right) \right] \leq \exp \left( \hat{C}_2 \lambda^4/T + \hat{C}_3 \lambda^3/\sqrt{T} \right). \tag{23}
\]

In summary, by (20) and (23), for all \(1 \leq u \leq \sqrt{T} \min \left\{ 1, 4C_0, \sqrt{\frac{3C^2_1}{8c_4}} \right\} \),
\[
\mathbb{P} \left( Z_T > u \right) \leq \hat{C} \lambda \exp \left( \hat{C}_2 \lambda^4/T + \hat{C}_3 \lambda^3/\sqrt{T} + C \left( \lambda^4/\sqrt{T} + \lambda^3 V_T \right) \right). \tag{24}
\]

Next, we compare \(1 - \Phi(\lambda)\) with \(1 - \Phi(u)\). Recall the following upper bound and lower bound on \(1 - \Phi(x) = \Phi(-x)\):
\[
\frac{1}{\sqrt{2\pi}(1+x)} \exp \left( -\frac{x^2}{2} \right) \leq \Phi(-x) \leq \frac{1}{\sqrt{\pi}(1+x)} \exp \left( -\frac{x^2}{2} \right), \quad x \geq 0.
\]

For all \(1 \leq u \leq \sqrt{T} \min \left\{ 1, 4C_0, \sqrt{\frac{3C^2_1}{8c_4}} \right\} \),
\[
1 \leq \frac{\int_{-\infty}^{\infty} \exp(-t^2/2)dt}{\int_{u}^{\infty} \exp(-t^2/2)dt} \leq \frac{\frac{1}{\sqrt{\pi}(1+u)} \exp(-u^2/2)}{\frac{1}{\sqrt{2\pi}(1+u)} \exp(-u^2/2)} = \sqrt{2} \frac{1+u}{1+\lambda} \exp((u^2 - \lambda^2)/2).
\]

From (17), we have
\[
u^2 - \lambda^2 = (u + \lambda)(u - \lambda)
\leq 2u(C\theta(uV_T + u^2/\sqrt{T})))
= 2C\theta(u^2V_T + u^3/\sqrt{T}).
\]

Therefore, with some constant \(\hat{C}_4 > 0\),
\[
\frac{\int_{-\infty}^{\infty} \exp(-t^2/2)dt}{\int_{u}^{\infty} \exp(-t^2/2)dt} \leq \exp \left( \hat{C}_4 \left( u^2V_T + u^3/\sqrt{T} \right) \right).
\]

We find that
\[
1 - \Phi(\lambda) \leq (1 - \Phi(u)) \exp \left( \hat{C}_4 \left( u^2V_T + u^3/\sqrt{T} \right) \right). \tag{25}
\]

By combining (24), (25), and (16), for all \(1 \leq u \leq \sqrt{T} \min \left\{ 1, 4C_0, \sqrt{\frac{3C^2_1}{8c_4}} \right\} \), there exists a constant \(\hat{C}_5 > 0\) such that
\[
\mathbb{P} \left( Z_T > u \right) \leq \hat{C} \lambda \exp \left( C \left( \lambda^3/\sqrt{T} + \lambda^4 V_T \right) + \hat{C}_2 \lambda^4/T + \hat{C}_3 \lambda^3/\sqrt{T} + \hat{C}_4 \left( u^2V_T + u^3/\sqrt{T} \right) \right)
\leq \hat{C} u \exp \left( \hat{C}_5 \left( u^2V_T + u^3/\sqrt{T} + u^3/T \right) \right).
\]

Applying the same argument to the martingale \(-Z_T\), we conclude the proof.

\(\square\)
I Proof of Lemma 4.6

Proof.

\[
\frac{E_{\nu}[N_{a,T}]}{T} = \frac{E_{\nu}[\sum_{s=1}^{T} E_{\nu}[1\{A_s = a\}|\mathcal{F}_{s-1}]]}{T} = E_{\nu}\left[\frac{\sum_{s=1}^{T} w_{a,t}}{T}\right].
\]

Note that the sequence \(\{\left(\sum_{s=1}^{T} w_{a,t}\right)/T\}\) is uniformly integrable from Proposition A.2. From Corollary G.2, we have that \(\left(\sum_{s=1}^{T} w_{a,t}\right)/T \xrightarrow{a.s.} w^*_a\). Therefore, from \(L^r\) convergence theorem (Proposition A.3), \(\lim_{T \to \infty} \frac{E_{\nu}[N_{a,T}]}{T} = w^*_a\). This concludes the proof.

J Additional Discussions and Related Work

J.1 Additional Literature on BAI

The stochastic MAB problem is a classical abstraction of the sequential decision-making problem (Thompson, 1933; Robbins, 1952; Lai and Robbins, 1985). BAI is a paradigm of the MAB problem (Even-Dar et al., 2006; Audibert et al., 2010; Bubeck et al., 2011). Though the problem of BAI itself goes back decades, variants go as far back as the 1950s Bechhofer et al. (1968). Another literature on ordinal optimization has been studied in the operation research community (Peng and Fu, 2016; Ahn et al., 2021), and a modern formulation was established in the 2000s (Chen et al., 2000; Glynn and Juneja, 2004), in which most of those studies consider the estimation of the optimal allocation ratio separately from the probability of misidentification.

In the BAI literature, there is another setting called BAI with fixed confidence (Jennison et al., 1982; Mannor and Tsitsiklis, 2004; Kalyanakrishnan et al., 2012; Wang et al., 2021). For the fixed confidence setting, Garivier and Kaufmann (2016) solves the problem in the sense that they provided a strategy whose upper bound matches the problem-dependent lower bound by solving an optimization problem at each step. The result is further developed by Degenne et al. (2019) to solve the solution of the two-player game by the no-regret saddle point algorithm. Besides, Shang et al. (2020) shows the asymptotic optimality of the Top Two Thompson Sampling (TTTS), proposed by Russo (2016) and Qin et al. (2017), in the fixed confidence setting. Wang et al. (2021) develops Frank-Wolfe-based Sampling (FWS) to complete the characterization of the complexity of fixed-confidence BAI with various types of structures among the arms. See Wang et al. (2021) for various techniques in the fixed-confidence setting and further comprehensive survey.

In contrast, there is less research on BAI with a fixed budget compared to BAI with fixed confidence. Following Audibert et al. (2010) and Bubeck et al. (2011), Gabillon et al. (2012) and Karnin et al. (2013) discuss the link between the fixed confidence and fixed budget settings. In some studies, the lower bounds are associated only with the gap \(\Delta\) (Audibert et al. (2010); Bubeck et al. (2011); Carpentier and Locatelli (2016) and Kaufmann et al. (2016) (Theorem 16)), rather than information-theoretic formulations in Kaufmann et al. (2016) (Theorem 12) and our Theorem 2.7. In Karnin et al. (2013), they propose the Sequential Halving (SH) strategy and show the performance guarantee

\[
\exp\left(-\frac{T}{8(\log K)H_2}\right).
\]

In Faella et al. (2020), they show that the complexity of the BAI with a fixed budget can be refined by using the variances as well as the gap. They introduce the complexity term

\[
H_{\sigma} = \max_{a \in [K] \setminus \{1\}} \frac{\sigma_a^2 + \sigma_a^2}{\Delta_a^2}
\]

and propose the strategy called Variance-Based Rejects (VBR). They prove a performance guarantee of VBR of the form

\[
\exp\left(-\frac{T}{2K(\log K)H_\sigma}\right).
\]

Their results suggest that the complexities of Audibert et al. (2010); Karnin et al. (2013) have some room for improvement depending on the variance of the distribution.

However, the tightest lower bound and the performance guarantee achieving the problem-dependent lower bound have been long-standing open problems.
J.2 Difference between Limit Experiments and Limit Decision-making Frameworks

For a parameter $\theta_0 \in \mathbb{R}$ and $T$ i.i.d. observations, the limit experiments framework considers local alternatives $\theta = \theta_0 + h/\sqrt{T}$ for a constant $h \in \mathbb{R}$ (van der Vaart, 1991, 1998). Then, we can approximate the statistical experiment by the Gaussian distribution and discuss the optimality of statistical procedures under the approximation. Hirano and Porter (2009) relates the asymptotic optimality of statistical decision rules (Manski, 2000, 2002, 2004; Dehejia, 2005) to the limits of experiments framework. This framework is further applied to policy learning, such as Kitagawa and Tetenov (2018) and Athey and Wager (2017). Although Hirano and Porter (2020) insists that this local experiment arguments can be applied to adaptive experimental designs, we consider that it cannot be applied to BAI.

The limit experiments arguments are based on the central limit theorem. On the other hand, taking the parameter $\theta = \theta_0 + h/\sqrt{T}$ will not give us the problem-dependent analysis; that is, the instance is not fixed as $T$ grows large. Therefore, a naive application of the information-theoretical result like Proposition 2.1 does not provide a lower bound that is valid for the problem-dependent analysis. To match the lower bound of Kaufmann et al. (2016), we need to consider large deviation bound, not the central limit theorem. However, the conventional large deviation bound cannot be applied to BAI strategies owing to the adaptive sampling strategy.

In other words, the limit experiment framework first applies the Gaussian approximation and then discusses the efficiency under the approximation, where efficiency arguments complete within the Gaussian distribution. On the other hand, in our limit decision-making, we derive the lower bound of an event under the true distribution. Then, we approximate it by considering the limit of the gap. Therefore, in limit decision-making, we first consider the optimality for the true distribution and find the optimal strategy in the sense that the upper bound matches the lower bound when the gap goes to zero.

J.3 Literature on Causal Inference

The AIPW estimator, which is also referred to as a doubly robust (DR) estimator when the allocation probability is unknown, plays an important role in treatment effect estimation (Robins et al., 1994; Hahn, 1998; Bang and Robins, 2005b; Dudik et al., 2011; van der Laan and Lendle, 2014; Luedtke and van der Laan, 2016). The AIPW estimator also plays an important role in double/debiased machine learning literature because it reduces the sensitivity of the nuisance parameters (Chernozhukov et al., 2018; Ichimura and Newey, 2022).

When constructing AIPW estimator with samples obtained from adaptive experiments including BAI strategies, a typical construction is to use sample splitting and martingales (van der Laan, 2008; Hadad et al., 2021; Kato et al., 2020, 2021). Howard et al. (2021), Kato et al. (2020), and provide non-asymptotic confidence intervals of the AIPW or DR estimator, which do not bound a tail probability in large deviation as ours. The AIPW estimator is also used in the recent bandit literature, mainly in regret minimization (Dimakopoulou et al., 2021; Kim et al., 2021). Hadad et al. (2021), Bibaut et al. (2021), and Zhan et al. (2021) consider the off-policy evaluation using observations obtained from regret minimization algorithms.

J.4 Other Related Work

Balsubramani and Ramdas (2016) and Howard et al. (2021) propose sequential testing using law of iterated logarithms and discuss the optimality of sequential testing based on the arguments of Jamieson et al. (2014).

In addition to Fan et al. (2013, 2014), there are also other studies that use martingales for obtaining tight bounds (Cappé et al., 2013; Juneja and Krishnasamy, 2019; Howard et al., 2021; Kaufmann and Koolen, 2021), where some of them apply change-of-measure techniques.

J.5 Future Direction

As is in BAI with fixed confidence, our future direction is to develop strategies for various settings, such as linear (Hoffman et al., 2014; Liang et al., 2019; Katz-Samuels et al., 2020), combinatorial (Chen et al., 2014), and contextual bandits (Russac et al., 2021; Kato and Ariu, 2021). A natural question is whether a complete characterization is possible under the large gap.
K Simulation Studies

In order to check the effectiveness of the proposed method, we conduct in this section numerical experiments under the two-armed Gaussian bandits (Appendix K.1) and multi-armed \((K \geq 3)\) bandits (Appendix K.2–K.4). For multi-armed bandit cases, we experiment on Gaussian bandits with heterogeneous variances (Appendix K.2), Gaussian bandits with equal variances (Appendix K.3), and Bernoulli bandits (Appendix K.4).

K.1 Two-armed Gaussian Bandits

We compare the proposed RS-AIPW (RA) strategy with the alpha-elimination (Alpha, Kaufmann et al., 2014, 2016) and uniform sampling strategies (Uniform). The alpha-elimination strategy is an oracle strategy, which assumes that the variances are known. See Kaufmann et al. (2014, 2016) for more details of the alpha-elimination strategy. In the uniform sampling strategy, we select arm 1 if the round is odd and select 2 otherwise; finally, we recommend an arm with the highest average reward defined as \(\hat{\mu}_{a,T+1}\) in Section 3. Besides, we also investigate the performances of the following two additional strategies:

**RS-DR (RD) strategy:** We replace the AIPW estimator in the RS-AIPW strategy with the DR estimator defined as
\[
\hat{\mu}_{a,T} = \frac{1}{T} \sum_{t=1}^{T} \hat{X}_{a,t}^\gamma, \quad \hat{X}_{a,t}^\gamma = \frac{1}{1 + \sum_{s=1}^{t-1} \mathbb{1}[A_s = a]} + \hat{\mu}_{a,t}.
\]

**RS-IPW (RI) strategy:** We replace the AIPW estimator in the RS-AIPW strategy with the IPW estimator defined as
\[
\hat{\mu}_{a,T} = \frac{1}{T} \sum_{t=1}^{T} \hat{X}_{a,t}^\gamma, \quad \hat{X}_{a,t}^\gamma = \frac{1}{1 + \sum_{s=1}^{t-1} \mathbb{1}[A_s = a]} X_{a,t}.
\]

**RS-SA (RS) strategy:** We replace the AIPW estimator in the RS-AIPW strategy with the simple sample average defined as
\[
\hat{\mu}_{a,T} = \frac{1}{T} \sum_{t=1}^{T} \mathbb{1}[A_t = a] X_{a,t}.
\]

The DR estimator replaces the allocation probability \(w_{a,t}\) with its estimator. The IPW estimator does not use the adjustment term \(\hat{\mu}_{a,t}\). The sample average corresponds to the IPW estimator whose allocation probability is replaced with its estimator \(\frac{1}{T} \sum_{t=1}^{T} \mathbb{1}[A_t = a] X_{a,t}\) because \(\hat{\mu}_{a,T}^{SA}\) can be rewritten as
\[
\hat{\mu}_{a,T}^{SA} = \frac{1}{T} \sum_{t=1}^{T} \mathbb{1}[A_t = a] X_{a,t}.
\]

Besides, to stabilize the allocation probability \(w_{a,t}\), instead of directly using \(w_{a,t}\), we use
\[
w_{a,t} = \gamma_t \frac{1}{2} + (1 - \gamma_t) w_{a,t},
\]
for \(\gamma_t\) such that \(\gamma_t \rightarrow 0\) as \(t \rightarrow \infty\). This prevents \(w_{a,t}\) from being some extreme value. Note that \(w_{a,t}^{\gamma_t} \xrightarrow{a.s.} w_a^*\) if \(w_{a,t} \xrightarrow{a.s.} w_a^*\). In this experiments, we use \(w_{a,t}^{\gamma_t}\) with \(\gamma_t = \frac{1}{\sqrt{t}}\) and 100 initialization rounds for the RS-AIPW, RS-DR, RS-IPW, and RS-SA strategies.

We consider the following eight sample scenarios:

- **Scenario 1** \(\mu_1 = 0.05, \mu_2 = 0.01, \sigma_1^2 = 1, \text{ and } \sigma_2^2 = 0.2\);
- **Scenario 2** \(\mu_1 = 0.05, \mu_2 = 0.01, \sigma_1^2 = 1, \text{ and } \sigma_2^2 = 0.1\);
- **Scenario 3** \(\mu_1 = 0.05, \mu_2 = 0.03, \sigma_1^2 = 1, \text{ and } \sigma_2^2 = 0.2\);
- **Scenario 4** \(\mu_1 = 0.05, \mu_2 = 0.03, \sigma_1^2 = 1, \text{ and } \sigma_2^2 = 0.1\);
- **Scenario 5** \(\mu_1 = 0.8, \mu_2 = 0.75, \sigma_1^2 = 5, \text{ and } \sigma_2^2 = 3\);
- **Scenario 6** \(\mu_1 = 0.8, \mu_2 = 0.75, \sigma_1^2 = 5, \text{ and } \sigma_2^2 = 1\);
- **Scenario 7** \(\mu_1 = 0.8, \mu_2 = 0.79, \sigma_1^2 = 5, \text{ and } \sigma_2^2 = 3\);
- **Scenario 8** \(\mu_1 = 0.8, \mu_2 = 0.79, \sigma_1^2 = 5, \text{ and } \sigma_2^2 = 3\);
Scenario 8 \( \mu_1 = 0.8, \mu_2 = 0.79, \sigma_1^2 = 5, \) and \( \sigma_2^2 = 1. \)

We set \( T = 3,000 \) and ran 10,000 independent trials for each setting. Although we set \( T = 3,000 \), we save the recommended arm for each \( t \in \{1,2,\ldots,3000\} \). Then, by taking the average over 10,000 independent trials, we compute the empirical probability of identification for \( t \in \{1,2,\ldots,3000\} \). The results of the experiments are shown in Figure 1.

We can confirm that the RS-AIPW (RA), RS-DR (RD), and RS-SA (RS) strategies perform as well as the alpha-elimination. On the other hand, the uniform sampling and RS-IPW strategies show sub-optimal results. The sub-optimal performance of the RS-IPW strategy can be considered that the IPW estimator has a larger variance than that of the AIPW estimator; in fact, the upper bound of the RS-IPW strategy does not match the lower bound, as will be shown in the following.

As well as Lemma 4.5, we can show the following corollary.

**Corollary K.1.** Under the RS-IPW strategy, for any \( \delta > 0 \), there exists \( T_0 \) such that for all \( T > T_0 \),

\[
\mathbb{E} \left[ \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}_\nu \left( \left( \hat{X}_{1,t} - \hat{X}_{2,t} - \Delta \right)^2 | F_{t-1} \right) - 1 \right] \leq \delta, \quad \text{where } \kappa = \frac{\mathbb{E}_\nu[X_{1,t}^2]}{w_1^2} + \frac{\mathbb{E}_\nu[X_{2,t}^2]}{w_2^2}.
\]

Thus, if we use the RS-IPW strategy, we cannot achieve the lower bound owing to the variance \( \kappa \), which is different from that of Lemma 4.5.

We conjecture that the reason why the RS-DR strategy performs well is that the re-estimated allocation probability mitigates the fluctuation of the allocation probability \( w_{a,t} \). A similar phenomenon is reported by Kato et al. (2021) in the context of off-policy evaluation as a paradox because even if we know the true allocation probability, replacing it with an estimator improves the performance.

### K.2 Multi-armed Gaussian Bandits with Heterogeneous Variances

We conduct experiments for multi-armed bandit models following Gaussian distributions with heterogeneous variances. The true variance is generated from the uniform distribution on \([0,1]\) for each arm. The expected reward of the best arm is fixed at \( \mu_1 = 1 \). The variances are generated from the uniform distribution on \([0,1]\). For the expected rewards of sub-optimal arms, we consider the following two cases:

**Case 1:** The number of arms is set to \( K \in \{3,5,10\} \). The expected rewards of sub-optimal arms are drawn from the uniform distribution with the support \([1-\Delta,0.99]\), where \( \Delta \) is chosen from \([0.01,0.05,0.1]\).

**Case 2:** The number of arms is set to \( K \in \{10,30,50\} \). The expected reward of the second best arm, \( \mu_2 \), is chosen from \([0.90,0.95,0.99]\). The other expected rewards are drawn from the uniform distribution with the support \([0,\mu_2]\).

Note that Case 1 corresponds to a situation considered in our theoretical analysis; that is, the differences between all of the expected rewards of the best and sub-optimal arms are bounded by small gap. On the other hand, in Case 2, we consider a more realistic scenario where we guarantee a small gap only between the best and second arms and the other gaps can be both small and large.

In addition to the RS-DR (RD), RS-SA (RS), and Uniform strategies used in Appendix K.1, we also compare the RS-AIPW (RA) with sequential halving (SH) (Karnin et al., 2013) and UGapEb (Gabillon et al., 2012). For the RS-AIPW, RS-DR, and RS-SA strategies, we pull each arm 10 times for initialization. We employ the two settings for the budget, \{1000,2500\}. For each case, we conduct 100 trials and employ the proportion of incorrect answers returned by BAI strategies as the performance metrics. This proportion can be considered as an estimate of the probability of misidentification. Therefore, the lower value of the percentage implies a better performance. The results are shown in Tables 1 and 2.

As shown in the results of Appendix K.1, there is room for improvement in the performance of the RS-AIPW, while the RS-DR and RS-SA show preferable performances. As mentioned in Appendix K.1, we guess that it is possible to show large deviation performance guarantees for the RS-DR and RS-SA, which will be proved via asymptotic optimality for the RS-AIPW as Hirano et al. (2003) and Hahn et al. (2011) show the asymptotic normality.

### K.3 Multi-armed Gaussian Bandits with Equal Variances

Next, we conduct experiments using bandit models following Gaussian distributions with equal variances. We fix the variances at 1 for all arms. The expected reward of the best arm is fixed at \( \mu_1 = 1 \). For the expected rewards of sub-optimal arms, we consider the following two cases:
Figure 1: Results of the two-armed Gaussian bandits. We compute the empirical probability of misidentification. Note that the result of RD is overlapped with that of the RS.
Case 3: The number of arms is set to $K \in \{3, 5, 10\}$. The expected rewards of sub-optimal arms are drawn from the uniform distribution with the support $[1 - \Delta, 0.99]$, where $\Delta$ is chosen from $\{0.01, 0.05, 0.1\}$.

Case 4: The number of arms is set to $K \in \{10, 30, 50\}$. The expected reward of the second best arm, $\mu_2$, is chosen from $\{0.90, 0.95, 0.99\}$. The other expected rewards are drawn from the uniform distribution with the support $[0, \mu_2]$.

We compare RS-AIPW (RA), RS-DR (RD), RS-SA (RS), UGapEb, sequential halving (SH), and Uniform strategies. The other settings are the same as that of Appendix K.2. Note that Case 3 and Case 4 correspond to Case 1 and Case 2 in Appendix K.2, respectively. The results are shown in Tables 3 and 4.

K.4 Multi-armed Bernoulli Bandits

Finally, we conduct experiments using bandit models following Bernoulli distributions. Similarly to Appendix K.2 and K.3, the expected reward of the best arm is fixed at $\mu_1 = 0.9$. For the expected rewards of sub-optimal arms, we consider the following two cases:

Case 5: The number of arms is set to $K \in \{3, 5, 10\}$. The expected rewards of sub-optimal arms are drawn from the uniform distribution with the support $[0.9 - \Delta, 0.89]$, where $\Delta$ is chosen from $\{0.01, 0.05, 0.1\}$.

Case 6: The number of arms is set to $K \in \{10, 30, 50\}$. The expected reward of the second best arm, $\mu_2$, is chosen from $\{0.80, 0.85, 0.89\}$. The other expected rewards are drawn from the uniform distribution with the support $[0, \mu_2]$.

We compare RS-AIPW (RA), RS-DR (RD), RS-SA (RS), UGapEb, sequential halving (SH), and Uniform strategies. The other settings are the same as that of Appendix K.2 and K.3. Note that Case 5 and Case 6 correspond to Case 1 (or Case 3) and Case 2 (or Case 4) in Appendix K.2 (or Appendix K.3), respectively. The results are shown in Tables 5 and 6.

K.5 Discussion on the Experimental Results

The results of the simulation studies show that, contrary to the theoretical expectation, the RS-AIPW (RA) strategy does not perform very well. This may be due to the instability of the arm allocations using the random sampling rule. It is possible that the randomness deteriorates the performance of the AIPW estimator. From the theoretical results, we still expect that the RS-AIPW strategy will outperform the other methods, such as the UGapEb strategy, given the huge budget and a small gap, but we could not show the case due to the computational cost.

On the other hand, the RS-DR (RD) strategy, which replaces the inverse probability in the RS-AIPW strategy with an estimator, shows good empirical performance, as reported by research on causal inference Kato et al. (2021). In addition, the RS-SA (RS) strategy also has good performance. We introduce the RS-AIPW strategy for the convenience of theoretical analysis, but it may be preferable to use other methods, such as the RS-DR and RS-SA strategies, in practice.

We conjecture that the RS-DR and RS-SA strategies also have the same optimal asymptotically optimal properties as our proposed RS-AIPW strategy. However, since we cannot use large deviation bound for martingales to investigate the asymptotic properties of the RS-DR and RS-SA strategies, the analysis becomes difficult owing to the sample dependency. The results of Hirano et al. (2003), Hahn et al. (2011), and Chernozhukov et al. (2018) may be helpful for solving this problem. The authors show the asymptotic distributions of the sample means and DR estimators by going through that of the AIPW estimator. Then, from the derived asymptotic distribution, the authors also discuss that the attained asymptotic variance is identical to that of the AIPW estimator, which is also equal to efficiency bound (Bickel et al., 1998). Investigating the asymptotic properties of the RS-DR and RS-SA strategies is a future task.
### Table 1: Results of the multi-armed Gaussian bandits with heterogeneous variances. **Case 1:** there is a small gap between the best arm and all the other arms.
