Abstract

It is well known that if \( m \) balls (jobs) are placed sequentially into \( n \) bins (servers) according to the ONE-CHOICE protocol – choose a single bin in each round and allocate one ball to it – then, for \( m \gg n \), the gap between the maximum and average load diverges. Many refinements of the ONE-CHOICE protocol have been studied that achieve a gap that remains bounded by a function of \( n \), for any \( m \). However most of these variations, such as TWO-CHOICE, are less sample-efficient than ONE-CHOICE, in the sense that for each allocated ball more than one sample is needed (in expectation).

We introduce a new class of processes which are primarily characterized by “filling” underloaded bins. A prototypical example is the PACKING process: At each round we only take one bin sample, if the load is below the average load, then we place as many balls until the average load is reached; otherwise, we place only one ball. We prove that for any process in this class the gap between the maximum and average load is \( O(\log n) \) for any number of balls \( m \). For the PACKING process, we also prove a matching lower bound. We also prove that the PACKING process is more sample-efficient than ONE-CHOICE, that is, it allocates on average more than one ball per sample. Finally, we also demonstrate that the upper bound of \( O(\log n) \) on the gap can be extended to the CACHING process (a.k.a. memory protocol) studied by Mitzenmacher, Prabhakar and Shah (2002).

Keywords— Balls-into-bins, balanced allocations, potential functions, heavily loaded, gap bounds, maximum load, memory, two-choices, weighted balls.

1 Introduction

We consider the sequential allocation of \( m \) balls (jobs or data items) to \( n \) bins (servers or memory cells), by allowing each ball to choose from a set of randomly sampled bins. The goal is to allocate balls efficiently, while also keeping the load distribution balanced. The balls-into-bins framework has found numerous applications in hashing, load balancing, routing, but is also closely related to more theoretical topics such as randomized rounding or pseudorandomness (we refer to the surveys 26 and 20 for more details).

A classical algorithm is the \( d \)-CHOICE process introduced by Azar et al. [1] and Karp et al. [13], where for each ball to be allocated, we sample \( d \geq 1 \) bins uniformly and then place the ball in the least loaded of the \( d \) sampled bins. It is well-known that for the ONE-CHOICE process \( (d = 1) \), the gap between the maximum and average load is \( \Theta(\sqrt{m/n \cdot \log n}) \), when \( m \geq n \log n \). In particular, this gap grows significantly as \( m \gg n \). For \( d = 2, [1] \) proved that the gap is only \( \log_2 \log n + O(1) \) for \( m = n \). This result was generalized by Berenbrink et

*Some results from the paper were presented at SODA 2022 [15].

Thus, for any $\beta$ using Two-Choice where each ball is allocated using One-Choice regarded as more sample-efficient and robust. Two-Choice sampled bins. Such processes make fewer assumptions than in their ability to sample two bins, sample uniformly or distinguish between the load of the sampled bins. Such processes make fewer assumptions than Two-Choice and can thus be regarded as more sample-efficient and robust.

One example of such an allocation process is the $(1 + \beta)$-process analyzed by Peres et al. [22], where each ball is allocated using One-Choice with probability $1 - \beta$ and otherwise is allocated using Two-Choice. The authors proved that for any $\beta \in (0, 1]$, the gap is $O(\frac{\log n}{\beta^2} + \frac{\log (1/\beta)}{\beta})$; thus for any $\beta = \Omega((1/n))$, the gap is $O(\frac{\log n}{\beta^2})$. Hence, only a “small” fraction of Two-Choice rounds are enough to inherit the property of Two-Choice that the gap is independent of $m$. A similar class of adaptive sampling schemes (where, depending on the loads of the samples so far, the ball may or may not sample another bin) was analyzed by Czumaj and Stemann [5], but their results hold only for $m = n$.

Another important process is 2-Thinning, which was studied in [8] [12]. In this process, each ball first samples a bin uniformly and if its load is below some threshold, the ball is placed into that sample. Otherwise, the ball is placed into a second bin sample, without inspecting its load. In [8], the authors proved that for $m = n$, there is a fixed threshold which achieves a gap of $O(\sqrt{\frac{\log n}{\log \log n}})$. This is a significant improvement over One-Choice, but also the total number of samples is greater than one per ball. Similar threshold processes have been studied in queuing [7], [18] Section 5] and discrepancy theory [6]. For values of $m$ sufficiently larger than $n$, [9] and [14] prove some lower and upper bounds for a more general class of adaptive thinning protocols (here, adaptive means that the choice of the threshold may depend on the load configuration). Related to this line of research, the authors of [14] also analyze a so-called Quantile-process, which is a version of 2-Thinning where the ball is placed into a second sample only if the first bin has a load which is at least the median load.

Finally, we mention the Caching process (also known as memory-protocol) analyzed by Mitzenmacher et al. [19], which is essentially a version of the Two-Choice process with cache. At each round, we take a uniform sample but we also have access to a cache. Then the ball is placed in the least loaded of the sampled and the bin in the cache, and after that the cache is updated if needed. It was shown in [19] that for $m = n$, the process achieves a better gap than Two-Choice. Luczak and Norris [16] analyzed the related “supermarket” model with memory, in the queuing setting.

From a more technical perspective, apart from analyzing a large class of natural allocation processes, an important question is to understand how sensitive the gap is to changes in the allocation probability vector. To this end, [22] formulated general conditions on the probability vector, which, when satisfied in all rounds, imply a small gap bound. These were then later applied not only to the $(1 + \beta)$-process, but also to analyze a “graphical” allocation model where a pair of bins is sampled by picking an edge of a graph uniformly at random. Other works which study perturbations on the probability vector are: allocations on hypergraphs [11], balls-into-bins with correlated choices [25]; or balls-into-bins with hash functions [3].

Our Results. We introduce the Packing process, where at each round we only take one bin sample, if the load is below the average load, then we place as many balls until the average load is reached; otherwise, we place only one ball (see Fig. 2 in Section 3.2). The ability of Packing to bring the load of an underloaded bin up to the average in one step is roughly what we mean by “filling”. We formulate two conditions, $\mathcal{P}$ and $\mathcal{W}$ which give rise to a broader class of allocation processes with this “filling” behavior, we call these Filling Processes. Very roughly, $\mathcal{P}$ stipulates that a procedure is used to sample a single bin in each round that is not more biased towards overloaded bins than the uniform distribution. Again, very roughly, $\mathcal{W}$
states that if we sample an underloaded bin then we allocate the amount of balls that would bring that bin up to the average load, however we may distribute them *almost* arbitrarily over the underloaded bins; otherwise, we allocate one ball.

As our first main result, we prove that if $\mathcal{P}$ and $\mathcal{W}$ both hold, then for any round $m$, a gap bound of $O(\log n)$ follows. Note that from here on, we will generally use $m$ to denote the number of rounds, which may be different (i.e., smaller than) the number of total balls allocated. While it is easy to show that PACKING meets the two conditions, some care is needed to apply the framework to CACHING (a.k.a. memory-protocol) due to its use of the cache, which creates strong correlations between the allocation of any two consecutive balls. We also show that filling processes with uniform probability vectors, such as PACKING, are more sample-efficient than ONE-CHOICE, while still achieving an $O(\log n)$ gap. This matches the gap bound of the $(1 + \beta)$-process for constant $\beta \in (0,1)$, which requires strictly more than one samples per ball, demonstrating the “power of filling” in maintaining balanced allocations. We further investigate this phenomenon, by analyzing two variants of PACKING: (i) TIGHT-PACKING, where the filling balls are adversarially allocated to the highest underloaded bins and (ii) BIASED-PACKING, where the bins may be selected using a probability vector that majorizes ONE-CHOICE. We show that both of these have a gap that is independent of $m$.

For PACKING, we also prove a matching lower bound on the gap of $\Omega(\log n)$ for any $m = \Omega(n \log n)$. Our results on the gap are summarized in Table 1.

Table 1: Overview of the Gap achieved (with probability at least $1 - n^{-1}$ for upper bounds and at least a positive constant for lower bounds), by different allocation processes considered in this work (and others). All stated bounds hold asymptotically; upper bounds hold for all values of $m$, while lower bounds may only hold for certain values of $m$. Cells shaded in green are new results.

**Proof Overview.** To prove a gap bound for filling processes, we consider an exponential potential function $\Phi^t$ with parameter $\alpha > 0$ (a variant of the one used in [22, 24]). This potential function considers only bins that are overloaded by at least two balls; thus it is blind to the load configuration across underloaded bins. We upper bound $E \left[ \Phi^{t+1} \mid \Phi^t \right]$ by an expression that is maximized if the process uses the uniform distribution for picking a bin (see Lemma 4.1). We then use this upper bound to deduce that: (i) in many rounds, the potential drops by a factor of at least $1 - \Omega(\frac{n}{m})$, and (ii) in other rounds, the potential increases by a factor of at most $1 + O(\frac{\alpha^2}{m})$ (see Lemma 4.2). Taking $\alpha$ sufficiently small and constructing a suitable super-martingale, we conclude that $E \left[ \Phi^t \right] = O(n)$. The desired gap bound is then implied by Markov’s inequality.

**Organization.** In Section 2 we define some basic mathematical notation needed for our analysis and introduce some previously studied balanced allocation processes related to our work. In Section 3 we present our framework for filling processes and state our $O(\log n)$ gap bound and sample efficiency bound for PACKING. Following this we discuss the PACKING, TIGHT-PACKING, CACHING and BIASED-PACKING processes. In Section 4 we prove an $O(\log n)$ bound on the gap for filling processes and a bespoke bound for BIASED-PACKING (this is not a
filling process). In Section 5 we prove the gap bound for the so-called “unfolding” of a filling process, and then we prove that this applies to CACHING. The derivation of the lower bounds is given in Section 6. Our bounds on the sample efficiency of filling processes are then proved in Section 7. In Section 8, we empirically compare the gaps of the different processes. Finally, in Section 9, we conclude by summarizing our main results and pointing to some open problems.

2 Notation and Preliminaries

Let \( x^t \) denote load vector of the \( n \) bins at round \( t = 0, 1, 2, \ldots \) (the state after \( t \) rounds have been completed). So in particular, \( x^0 := (0, \ldots, 0) \). In many parts of the analysis, we will assume an arbitrary labeling of the \( n \) bins so that their loads at round \( t \) are ordered non-increasingly, i.e.,

\[ x_1^t \geq x_2^t \geq \cdots \geq x_n^t. \]

We now give a formal definition of the classical \( d \)-Choice process \([1, 13]\) for reference.

**\( d \)-Choice Process:**

**Iteration:** For each \( t \geq 0 \), sample \( d \) bins \( i_1, \ldots, i_d \) with replacement, independently and uniformly. Place a ball in a bin \( i_{\text{min}} \) satisfying \( x_{i_{\text{min}}}^t = \min_{1 \leq j \leq d} x_{i_j}^t \), breaking ties arbitrarily.

Mixing One-Choice with Two-Choice rounds at a rate \( \beta \), one obtains the \((1+\beta)\) process \([22]\):

**\((1+\beta)\) Process:**

**Parameter:** A probability \( \beta \in (0, 1] \).

**Iteration:** For each \( t \geq 0 \), with probability \( \beta \) allocate one ball via the Two-Choice process, otherwise allocate one ball via the One-Choice process.

The Quantile(\( \delta \)) process \([14]\) is another relaxation of Two-Choice and an instance of adaptive 2-Thinning.

**Quantile(\( \delta \)) Process:**

**Parameter:** A quantile \( \delta \in \{1/n, 2/n, \ldots, 1\} \).

**Iteration:** For each \( t \geq 0 \), sample two bins \( i_1 \) and \( i_2 \) with replacement, independently and uniformly at random, and update:

\[
\begin{cases}
    x_{i_1}^{t+1} = x_{i_1}^t + 1 & \text{if } i_1 \text{ is among the } \delta \cdot n \text{ most loaded bins,} \\
    x_{i_2}^{t+1} = x_{i_2}^t + 1 & \text{otherwise.}
\end{cases}
\]

Unlike the standard balls-into-bins processes, some of our processes may allocate more than one ball in a single round. To this end we define \( W^t := \sum_{i=1}^n x_i^t \) as the total number of balls that are allocated by round \( t \) (for \( d \)-Choice we allocate one ball per round, so \( W^t = t \); however our processes may allocate more than one ball in each round, that is \( W^t \geq t \)). We define the gap as \( \text{Gap}(t) := \max_{i\in[n]} x_i^t - \frac{W^t}{n} \), which is the difference between the maximum load and average load at round \( t \). When referring to the gap of a specific process \( P \), we write \( \text{Gap}_P(t) \) but may simply write \( \text{Gap}(t) \) if the process under consideration is clear from the context. Finally, we define the normalized load of a bin \( i \) as:

\[ y_i^t := x_i^t - \frac{W^t}{n}. \]

Further, let \( B^+_\uparrow := \{ i \in [n]: y_i^t \geq 0 \} \) be the set of overloaded bins, and \( B^T := [1,n] \setminus B^+_\uparrow \) be the set of underloaded bins. Following \([22]\), let \( (p_1^t, p_2^t, \ldots, p_n^t) \) be the probability vector of
an allocation process, where for every \( i \in [n] \), \( p_i^t \) is the probability that the process picks the \( i \)-th most heavily loaded bin round \( t \) for the allocation. We denote by \( i \in \pi^t \ [n] \) a sample of \([n]\) according to this vector \( p^t \). A special case of a probability vector is the uniform vector of One-Choice, which is \( p_i^t = p_i = \frac{1}{n} \) for all \( i \in [n] \) and \( t \geq 0 \). For two probability vectors \( p \) and \( q \) (or analogously, for two sorted load vectors), we say that \( p \) majorizes \( q \) if for all \( 1 \leq k \leq n \), \[ \sum_{i=1}^k p_i \geq \sum_{i=1}^k q_i. \]

We define \( \mathcal{F}^t \) as the filtration corresponding to the first \( t \) allocations of the process (so in particular, \( \mathcal{F}^t \) reveals \( x^t \)). For random variables \( Y, Z \) we say that \( Y \) is stochastically smaller than \( Z \) (or equivalently, \( Y \) is stochastically dominated by \( Z \)) if \( \Pr [Y \geq x] \leq \Pr [Z \geq x] \) for all real \( x \). Throughout the paper, we often make use of statements and inequalities which hold only for sufficiently large \( n \). For simplicity, we do not state this explicitly.

3 Our Results on Filling Processes

In this section we shall present our main results. In the first subsection we present the framework for filling processes, then state the gap bound (Theorem 3.1) and finally show they are sample-efficient (Theorem 3.2) under the additional assumption of sampling each bin uniformly. In Section 3.2 we introduce the PACKING process, which is our prototypical example of a filling process, and give a lower bound showing our general gap bound is essentially best possible. The TIGHT-PACKING process is also introduced as an example of a more adversarial process that nevertheless still fits our framework, and thus also has a logarithmic gap. Finally in Section 3.3 we introduce the CACHING process and a method we call “unfolding” that can extend the applicability of our gap result. In particular, although CACHING is not a filling process we show that a suitable unfolding of it is, and thus we obtain a gap bound for CACHING with a polynomial number of balls. Finally in Section 3.4 we introduce and analyze the BIASED-PACKING process which is not a filling process but highlights the power of filling, as the gap is still independent of \( m \).

3.1 Filling Processes

We now formally define the main class of processes studied in this paper. Recall that \( B^t_- := \{ i \in [n] : y_i^t < 0 \} \) is the set of underloaded bins after \( t \) rounds have been completed.

**Filling Processes:**
For each round \( t \geq 0 \), we sample a bin \( i = i^t \) and then place a certain number of balls to \( i \) (or other bins). More formally:

**Condition \( \mathcal{P} \):** For each round \( t \geq 0 \), pick an arbitrary labeling of the \( n \) bins such that \( y_1^t \geq y_2^t \geq \cdots \geq y_n^t \). Then let \( i = i^t \in \pi^t [n] \), where the probability vector \( p^t \) is majorized by the uniform distribution (ONE-CHOICE).

**Condition \( \mathcal{W} \):** For each round \( t \geq 0 \), with \( i \) being the bin chosen above:

- If \( y_i^t \geq 0 \) then allocate a single ball to bin \( i \).
- If \( y_i^t < 0 \) then allocate exactly \([-y_i^t]+1 \geq 2 \) balls to underloaded bins such that there can be at most two bins \( k_1, k_2 \in B^t_- \) where:

  (a) \( k_1 \in B^t_- \) receives \([-y_i^t]+1 \) balls (i.e., \( x_{k_1}^{t+1} = \lceil \frac{W^t_{k_1}}{n} \rceil + 1 \)),

  (b) \( k_2 \in B^t_- \) receives \([-y_i^t] \) balls (i.e., \( x_{k_2}^{t+1} = \lfloor \frac{W^t_{k_2}}{n} \rfloor \))

  (c) each \( j \in B^t_- \setminus \{ k_1, k_2 \} \) receives at most \([-y_j^t]-1 \) balls (i.e., \( x_{j}^{t+1} \leq \lfloor \frac{W^t_{j}}{n} \rfloor - 1 \)).

See **Fig. 1** for an illustration of the effect of condition \( \mathcal{W} \) if an underloaded bin is chosen.
Figure 1: Illustration of an allocation for a filling process. After the underloaded bin \( i \) is picked, \( \lceil -y^t_i \rceil + 1 = 6 \) balls are allocated. Only one bin \( k_1 \) receives \( \lceil -y^t_{k_1} \rceil + 1 \) balls and only one bin \( k_2 \) receives \( \lceil -y^t_{k_2} \rceil \) balls, i.e., at most one allocated bin attains a load in the orange region and at most one in the blue region. All other bins \( j \) receive at most \( \lceil -y^t_j \rceil - 1 \) balls.

We emphasize that in condition \( \mathcal{P} \) the distribution \( p^t \) may not only be time-dependent, but may also depend on the load distribution at round \( t \), that is, the filtration \( \mathcal{F}^t \). We point out that Condition \( \mathcal{W} \) seems both a bit technical and arbitrary. For clarity, observe that within one round Condition \( \mathcal{W} \) can make at most two formerly unloaded bins overloaded; one bin by at most two balls (case (a)) and one bin by at most one ball (case (b)). This could be further relaxed (and generalized) by allowing a constant number of bins to become overloaded by a constant number of balls. However, this would come at the cost of making the analysis more tedious, while the specific choice of condition \( \mathcal{W} \) already suffices to cover the processes defined later in this section.

Also, the allocation used in \( \mathcal{W} \) may depend on the filtration \( \mathcal{F}^t \). Thus the framework also applies in the presence of an adaptive adversary, which directs all the \( \lceil -y^t_i \rceil + 1 \) balls to be allocated in round \( t \) towards the “most loaded” underloaded bins (see Tight-Packing in Section 3.2). At the other end of the spectrum, there are natural processes which have a propensity to place these balls into “less loaded” underloaded bins. One specific, more complex example is the CACHING process, where due to the update of the cache after each single ball, the allocation is more skewed towards “less loaded” underloaded bins. However, as we shall discuss shortly, CACHING only satisfies \( \mathcal{P} \) and \( \mathcal{W} \) after a suitable “folding” of rounds.

Our main result is that filling processes have gap of order \( \log n \) with high probability.

**Theorem 3.1.** There exists a universal constant \( C > 0 \) such that for any allocation process satisfying conditions \( \mathcal{P} \) and \( \mathcal{W} \) at each round, and for any \( m \geq 1 \), we have

\[
\Pr \left[ \text{Gap}(m) \leq C \log n \right] \geq 1 - n^{-2}.
\]

This result is proven in Section 4 by analyzing an exponential potential function \( \Phi^m \) over the overloaded bins and eventually establishing that for any \( m \geq 1 \), \( \mathbb{E} [\Phi^m] = O(n) \). Then a simple application of Markov’s inequality yields the desired result for the gap.

Recall that \( W^t = \sum_{i \in [n]} x^t_i \) is the total number of balls allocated by round \( t \) and \( S^t \) is the number of bins sampled up to time \( t \), thus \( S^t = t \) for PACKING. We define the sample efficiency by

\[
\eta^t = \frac{W^t}{S^t},
\]

this is the average balls placed per bin sampled during the first \( t \) rounds. Observe that for any \( t \geq 1 \) we have \( \eta^t = 1 \) for ONE-CHOICE and \( \eta^t = 1/2 \) for TWO-CHOICE deterministically. Our next result shows that filling processes with uniform probability vectors are more sample-efficient than ONE-CHOICE.
**Theorem 3.2.** There exist universal constants $c, C > 0$ such that for any process satisfying $\mathcal{W}$ and $\mathcal{P}$ with a uniform probability vector at each round, and for any $m \geq 2$ we have

$$1 + c \leq \mathbb{E}[\eta^m] \leq C.$$  

The key idea in the proof is an observation that within any window of $n$ rounds, in a constant proportion of the rounds there is either a large number of underloaded bins or the absolute value potential function is linear. If the first event holds in a round, then we pick an underloaded bin with constant probability, thus conditional on this event the expected number of balls increases by more than one since we allocate at least two balls to an underloaded bin. The increase in the expected number of balls allocated conditional on the second event comes from a direct relationship between the number of balls allocated in a round and the absolute value potential.

For the lightly loaded case $m = n$, we can obtain a tighter upper bound on the gap, by observing that for a bin to have a gap of $g$ it must be chosen as an overloaded bin at least $g - 2$ times. Hence, by the maximum load of ONE-CHOICE for $m = n$ (e.g., [21, Lemma 5.1]), we get:

**Observation 3.3.** For any process satisfying $\mathcal{W}$ and $\mathcal{P}$ we have

$$\Pr \left[ \text{Gap}(n) \leq 3 \cdot \frac{\log n}{\log \log n} \right] \geq 1 - n^{-1}.$$  

### 3.2 The Packing Process

A natural example of a process satisfying $\mathcal{P}$ and $\mathcal{W}$ is PACKING, which places “greedily” as many balls as possible into an underloaded bin (i.e., a bin with load below average).

**Observation 3.3.** For any process satisfying $\mathcal{W}$ and $\mathcal{P}$ we have

$$\Pr \left[ \text{Gap}(n) \leq 3 \cdot \frac{\log n}{\log \log n} \right] \geq 1 - n^{-1}.$$  

#### The Packing Process

**Packing Process:**

**Iteration:** For each $t \geq 0$, sample a uniform bin $i$, and update its load:

$$x_{t+1}^i = \begin{cases} 
  x_t^i + 1 & \text{if } x_t^i \geq \frac{W_t}{n}, \\
  \left\lceil \frac{W_t}{n} \right\rceil + 1 & \text{if } x_t^i < \frac{W_t}{n}.
\end{cases}$$

See Fig. 2 for an illustration of PACKING. It is simple to show that this is a filling process.

**Figure 2:** Illustration of the two different possibilities in a single round of the PACKING process: (left) allocating a single ball to an overloaded bin and (right) filling an underloaded bin.

**Lemma 3.4.** The PACKING process satisfies conditions $\mathcal{P}$ and $\mathcal{W}$

**Proof.** The PACKING process picks a uniform bin $i$ at each round $t$, thus it satisfies $\mathcal{P}$. Furthermore, if $y_t^i < 0$, it allocates exactly $\left\lceil -y_t^i \right\rceil + 1$ balls to bin $i$; otherwise, it allocates one ball to $i$, and thus $\mathcal{W}$ is also satisfied.  

---

**Notes:**

- **Diagram:** The diagram illustrates the two different possibilities in a single round of the PACKING process: (left) allocating a single ball to an overloaded bin and (right) filling an underloaded bin.

- **Observation:** PACKING satisfies the conditions $\mathcal{P}$ and $\mathcal{W}$ when $m = n$.
The Packing process is quite similar to One-Choice, however, Theorem 3.1 shows that it has a $O(\log n)$ gap. We also prove the following lower bound which shows that the upper bound is essentially best possible.

**Theorem 3.5.** For the Packing process, there exists a constant $\kappa > 0$ such that for any $m \geq \kappa n \log n$,

$$\Pr \left[ \text{Gap}(m) \geq \frac{\sqrt{\kappa}}{20} \cdot \log n \right] \geq \frac{1}{2}.$$

The Packing process arises naturally when one is trying to achieve a small gap from few bin queries or random samples. In contrast, the following process is rather contrived, as whenever an underloaded bin is chosen, balls can be placed into (possibly different) underloaded bins that have the highest load. However, it is interesting that even this process achieves a small gap, as we shall show it is a filling process.

**Tight-Packing Process:**

**Iteration:** For each $t \geq 0$, sample a uniform bin $i$, and update:

\[
\begin{cases}
  x_{i}^{t+1} = x_{i}^{t} + 1 & \text{if } x_{i}^{t} \geq \frac{W_{t}}{n}, \\
  \text{allocate } \lceil -y_{i}^{t} \rceil + 1 \text{ balls one by one into the bins } \ell \text{ with highest loads such that } x_{\ell}^{t+1} < \frac{W_{t}}{n}, & \text{except for one bin } j \text{ that gets } x_{j}^{t+1} = \lceil \frac{W_{t}}{n} \rceil + 1.
\end{cases}
\]

An equivalent (and more formal) description of Tight-Packing is the following: Assume the bin loads are decreasingly sorted $x_{1}^{t} \geq x_{2}^{t} \geq \cdots \geq x_{n}^{t}$. If the selected bin $i \in [n]$ is overloaded, then we allocate one ball in $i$. Otherwise, we update the load of the maximally loaded underloaded bin $j \in [n]$ at round $t$ to $x_{j}^{t+1} = \lceil \frac{W_{t}}{n} \rceil + 1$. Then the remaining $([-y_{i}^{t}] + 1) - ([y_{j}^{t}] + 1) = [-y_{i}^{t}] - [y_{j}^{t}] \geq 0$ balls (if there are any), are allocated to bins $j+1, j+2, \ldots, j+\ell$ for some integer $\ell \geq 0$, such that all bins $k \in [j+1, j+\ell - 1]$ have $x_{k}^{t+1} = \lceil \frac{W_{t}}{n} \rceil - 1$ and $x_{j+\ell}^{t+1} \in [x_{j+\ell}, \lceil \frac{W_{t}}{n} \rceil]$. See Fig. 3 for an illustration of the Tight-Packing process.

**Figure 3:** Illustration of the two different possibilities in a single round of the Tight-Packing process: (left) allocating a single ball to an overloaded bin and (right) allocating as many balls as the underload of the selected bin, to the most underloaded bins. Note that only one of the three bins where balls were allocated, attains a load of $\geq \lceil W^{t}/n \rceil$.

As promised we now show that this is also a filling process.

**Lemma 3.6.** The Tight-Packing process satisfies conditions $\mathcal{P}$ and $\mathcal{W}$.

**Proof.** The Tight-Packing process picks a uniform bin $i$ at each round $t$, thus it satisfies $\mathcal{P}$ further, the allocation satisfies the following properties regarding the allocation of balls.

First, in case of $y_{i}^{t} < 0$, then: (i) we allocate exactly $[-y_{i}^{t}] + 1$ balls, (ii) one bin receives $[-y_{i}^{t}] + 1$ balls (satisfying (a)), and (iii) every other bin $j$ receives a number of balls between $0, [-y_{i}^{t}] - 1$ (satisfying (c)). Secondly, in case of $y_{i}^{t} \geq 0$ we place one ball to $i$. Thus $\mathcal{W}$ is also satisfied. \[\square\]
3.3 Caching and Unfolding

The memory protocol was introduced by Mitzenmacher et al. [19] and works under the assumption that the address $b$ of a single bin can be stored or “cached”. The process is essentially a TWO-CHOICE process where the second sample is replaced by the bin in the cache.

**CACHING Process (a.k.a. Memory Protocol):**

**Iteration:** For each $t \geq 0$, sample a uniform bin $i$, and update its load (or of cached bin $b$):

- $x_{i}^{t+1} = x_{i}^{t} + 1$ if $x_{i}^{t} < x_{b}^{t}$ (also update cache $b = i$),
- $x_{i}^{t+1} = x_{i}^{t} + 1$ if $x_{i}^{t} = x_{b}^{t}$,
- $x_{b}^{t+1} = x_{b}^{t} + 1$ if $x_{i}^{t} > x_{b}^{t}$.

See Fig. 4 for an illustration of the CACHING process.

![Figure 4](image_url)

**Figure 4:** Illustration of the two different possibilities in a single round of the CACHING process: (left) allocating to the sampled bin and (right) updating the cache or allocating to the cache (shown in green).

As mentioned above, CACHING does not satisfy conditions $\mathcal{P}$ and $\mathcal{W}$ directly. The issue is that CACHING allocates only one ball at each round whereas, due to condition $\mathcal{W}$, a filling process may place several balls into underloaded bins in a single round. To overcome this issue, we define a so-called unfolding of a filling process. The filling process proceeds in rounds $0, 1, \ldots$, whereas the unfolding is a coupled process, which is encoded as a sequence of atomic allocations (each allocation places exactly one ball into a bin). Using this unfolding along with the gap bound for a filling process satisfying $\mathcal{W}$ and $\mathcal{P}$, we can then bound the number of atomic allocations with a large gap.

First, we define unfolding formally: Note that the unfolding of a process is not (completely) unique, as the allocations in $[W^{t-1}+1, W^{t}]$ of $U(P)$ can be permuted arbitrarily.

The next result shows that CACHING can be considered as a filling process after it has been “unfolded”.

**Lemma 3.7.** There is a process $P$ satisfying conditions $\mathcal{P}$ and $\mathcal{W}$, such that for a suitable unfolding $U = U(P)$, the process $U$ is an instance of CACHING.

Now, applying Theorem 3.1 to the unfolding of a filling process, and exploiting that in a balanced load configuration not too many atomic allocations can be created through unfolding, we obtain the following result:

**Lemma 3.8.** Fix any constant $c > 0$. Then for any filling process $P$ satisfying $\mathcal{W}$ and $\mathcal{P}$ there is a constant $C = C(c) > 0$ such that for any number of atomic allocations $m \geq 1$, with probability at least $1 - n^{-2}$, any unfolding $U = U(P)$ satisfies

$$|\{t \in [m]: \text{Gap}_U(t) \leq C \cdot \log n\}| \geq n^{-c} \cdot m \log m.$$
Hence for any $m$, all but a polynomially small fraction of the first $m$ atomic allocations in any unfolding of a filling process (e.g., CACHING) have a logarithmic gap. This behavior matches the one of the original filling process; the only limitation is that we cannot prove a small gap that holds for an arbitrarily large fixed atomic allocation $m$. However, if $m$ is polynomial in $n$, that is, $m \leq n^c$ for some constant $c > 0$, then Lemma 3.8 implies directly that with high probability, the gap at atomic allocation $m$ (and at all atomic allocations before) is logarithmic.

### 3.4 The Biased-Packing Process

We now consider a variant of the PACKING process, the Biased-Packing process, which has a bias placing towards overloaded bins. In particular, we consider the reverse probability vector $p$ of the Quantile($1/2$) process, i.e.,

$$p_i := \begin{cases} \frac{3}{2n} & \text{if } i \leq n/2, \\ \frac{1}{2n} & \text{otherwise.} \end{cases} \quad (3.1)$$

Then the Biased-Packing process is the same as the PACKING process but bins are sampled according to the probability vector $p$ above rather than the uniform distribution.

**Biased-Packing Process:**

**Iteration:** For each $t \geq 0$, sample a bin $i \in_p [n]$, where $p$ is given by (3.1), and update its load:

$$x_{t+1}^i = \begin{cases} x_t^i + 1 & \text{if } x_t^i \geq W_t n, \\ \lceil W_t n \rceil + 1 & \text{if } x_t^i < W_t n. \end{cases}$$

Note that the Biased-Packing process is not a filling process as its probability vector is not majorized by the uniform distribution. Although this process may look a bit contrived at first due to the way it selects a bin, we have chosen this as a representative of a broader range of processes whose probability vector majorizes ONE-CHOICE. In particular such probability vectors may occur, if the load information is noisy or outdated. Next we show that Biased-Packing has a gap bound that is independent of $m$.

**Proposition 3.9.** For the Biased-Packing process, for any $m \geq 1$

$$\mathbb{E} [\Delta^m] \leq 10n^2,$$

and hence,

$$\Pr \left[ \text{Gap}(m) \leq 10n^3 \right] \geq 1 - n^{-1}.$$

This result is very simple to prove and we do not claim that the bound is tight, however we include it as it illustrates the power of filling. In particular, if single balls are assigned sequentially according to the probability vector given by (3.1) then the gap will grow at least as fast as ONE-CHOICE, that is Gap($m$) = $\Omega(\sqrt{m \log n})$ for $m \gg n$. However the Biased-Packing process also “fills” underloaded bins, and it is this power that allows it to have a bounded gap - despite the best efforts of its unruly probability vector.

### 4 Upper Bounds on the Gap

In this section we prove our upper bounds on the gap. We begin in Section 4.1 by defining the exponential potential function and analyzing its behavior (depending on some other constraints). Then in Section 4.2 we use a super-martingale argument to show that the exponential potential function decreases, which eventually yields the desired gap bound in Theorem 3.1. Finally in Section 4.3 we bound the gap of the Biased-Packing by considering the absolute value potential.
4.1 Potential Function Analysis

We consider a version of the exponential potential function $\Phi^t$ which only takes bins into account whose load is at least two above the average load. This is given by

$$\Phi^t := \sum_{i : y_i^t \geq 2} \exp(\alpha \cdot y_i^t) = \sum_{i=1}^{n} \exp(\alpha \cdot y_i^t) \cdot 1_{\{y_i^t \geq 2\}},$$

where we recall that $y_i^t = x_i^t - \frac{W_i}{n}$ is the normalized load of bin $i$ at round $t$ and $\alpha > 0$ is a sufficiently small constant to be fixed later. Let $\Phi_i^t = \exp(\alpha \cdot y_i^t) \cdot 1_{\{y_i^t \geq 2\}}$ and thus $\Phi^t = \sum_{i=1}^{n} \Phi_i^t$. We will also use the absolute value potential:

$$\Delta^t := \sum_{i=1}^{n} |y_i^t|.$$

The next lemma provides a useful upper bound on the expected potential. It establishes that to bound $\mathbb{E}[\Phi^{t+1} \mid \mathcal{F}^t]$ from above, we may assume the probability vector $p^t$ is uniform.

**Lemma 4.1.** Consider any allocation process satisfying $\mathcal{P}$ and $\mathcal{W}$. Then for any round $t \geq 0$,

$$\mathbb{E}[\Phi^{t+1} \mid \mathcal{F}^t] \leq \frac{1}{n} \sum_{i=1}^{n} \Phi_i^t \cdot \left( \sum_{j : y_j^t < 1} e^{-\alpha(\lceil -y_j^t \rceil + 1)} + e^{-\frac{\alpha}{n}} \cdot (|B_{\geq 1}^t| - 1) + e^{\alpha - \frac{\alpha}{n}} \right) + e^{3\alpha},$$

where $B_{\geq 1}^t$ denotes the set of bins with load at least 1.

**Proof.** Recall that the filtration $\mathcal{F}^t$ reveals the load vector $x^t$. Throughout this proof, we consider the labeling chosen by the process in round $t$ such that $x_1^t \geq x_2^t \geq \cdots \geq x_n^t$ and $p^t$ being majorized by ONE-CHOICE (according to $\mathcal{P}$). We emphasize that for this labeling, $x_i^{t+1}$ may not be non-increasing in $i \in [n]$.

To begin, using $\Phi_i^{t+1} = e^{\alpha y_i^{t+1}} \cdot 1_{\{y_i^{t+1} \geq 2\}}$, we can split $\Phi^{t+1}$ over the $n$ bins as follows,

$$\mathbb{E}\left[\Phi^{t+1} \mid \mathcal{F}^t\right] = \sum_{j=1}^{n} \mathbb{E}\left[\Phi_j^{t+1} \mid \mathcal{F}^t\right].$$

Now consider the effect of picking bin $i$ for the allocation in round $t$ to the potential $\Phi^{t+1}$. Note that bin $i$ is chosen with probability equal to $p_i^t$. Observe that if bin $i$ satisfies $y_i^t < 1$, then it receives at most $\lceil -y_i^t \rceil + 1$ many balls in round $t$, thus $y_i^{t+1} \geq 2$ if and only if $y_i^t \geq 1$. Using condition $\mathcal{W}$ we distinguish between the following three cases based on how allocating to $i$ changes $\Phi_j^t$ for $j \neq i$ and for $j = i$:

**Case 1.A** $[y_i^t < 1, j \neq i, y_j^t < 1]$. We will allocate $\lceil -y_i^t \rceil + 1$ many balls to bins $k$ with $y_k^t < 1$ (not necessarily to $i$) subject to $\mathcal{W}$. This increases the average load by $((\lceil -y_i^t \rceil + 1)/n)$. Since $y_j^t < 1$, $\Phi_j^t = 0$. Further, by condition $\mathcal{W}$ we can increase the load of $y_j^t$ by at most $\lceil -y_j^t \rceil + 1$, hence, $\Phi_j^{t+1} = 0$. Therefore, $\Phi_j^{t+1} = \Phi_j^t \cdot e^{-\alpha(\lceil -y_j^t \rceil + 1)/n}$ for $j \neq i$.

**Case 1.B** $[y_i^t < 1, j \neq i, y_j^t \geq 1]$. As in Case 1a, we will allocate $\lceil -y_i^t \rceil + 1$ many balls to bins $k$ with $y_k^t < 1$ (not necessarily to $i$) subject to $\mathcal{W}$ which increases the average load by $((\lceil -y_i^t \rceil + 1)/n)$. Additionally, bin $j$ will receive no balls (by condition $\mathcal{W}$), thus $\Phi_j^{t+1} = \Phi_j^t \cdot e^{-\alpha(\lceil -y_j^t \rceil + 1)/n}$ for $j \neq i$.

**Case 2** $[y_i^t \geq 1, j \neq i]$. We allocate one ball to $i$, which increases the average load by $1/n$, and thus $\Phi_j^{t+1} = \Phi_j^t \cdot e^{-\alpha/n}$ for $j \neq i$, which again also holds for bins $j$ that do not contribute.
Case 3 \(j = i\). Finally, we consider the effect on \(\Phi_{i}^{t+1}\). Again if \(y_{i}^{t} < 1\), then \(\Phi_{i}^{t} = 0\) and \(\Phi_{i}^{t+1} = 0\). Otherwise, we have \(y_{i}^{t} \geq 1\) and we allocate one ball to \(i\), and thus

\[
\Phi_{i}^{t+1} = e^{\alpha(y_{i}^{t+1}) - \frac{n}{2}} 1_{\{y_{i}^{t+1} \geq 2\}} = e^{\alpha y_{i}^{t} 1_{\{y_{i}^{t+1} \geq 2\}}} \cdot e^{\frac{-n}{2}} \leq (e^{\alpha y_{i}^{t} 1_{\{y_{i}^{t} \geq 2\}}} + e^{2\alpha}) \cdot e^{\frac{-n}{2}},
\]

where the \(+e^{2\alpha}\) is added to account for the case where \(1 \leq y_{i}^{t} < 2\) and so \(\Phi_{i}^{t} = 0\) but \(0 < \Phi_{i}^{t+1} \leq e^{3\alpha - \frac{n}{2}}\). Thus in this case, \(\Phi_{i}^{t+1} \leq \Phi_{i}^{t} e^{\frac{n}{2}} + e^{3\alpha - \frac{n}{2}} \leq \Phi_{i}^{t} e^{\frac{n}{2}} + e^{3\alpha}\).

By aggregating the three cases above, and observing that \(\sum_{i=1}^{n} p_{i}^{t} \cdot e^{3\alpha} = e^{3\alpha}\), we see that

\[
\sum_{j=1}^{n} E[\Phi_{j}^{t+1} | \mathcal{F}^{t}] = \sum_{i=1}^{n} p_{i}^{t} \sum_{j=1}^{n} E[\Phi_{j}^{t+1} | \mathcal{F}^{t}, \text{ Bin } i \text{ is selected at round } t] \\
\leq \sum_{i=1}^{n} p_{i}^{t} \cdot 1_{\{y_{i}^{t} < 1\}} \sum_{j=1}^{n} \Phi_{j}^{t} \cdot e^{\frac{-n(-y_{i}^{t})}{n}} + \sum_{i=1}^{n} p_{i}^{t} \cdot 1_{\{y_{i}^{t} \geq 1\}} \sum_{j \neq i} \Phi_{j}^{t} \cdot e^{\frac{-n}{n}} \\
+ \sum_{i=1}^{n} p_{i}^{t} \cdot 1_{\{y_{i}^{t} \geq 1\}} \cdot \Phi_{i}^{t} \cdot e^{\frac{n}{2}} + e^{3\alpha} \tag{4.1}
\]

We will now rewrite [4.1] in order to establish that it is maximized if \(p\) is the uniform distribution. Adding \(\sum_{i=1}^{n} p_{i}^{t} \cdot 1_{\{y_{i}^{t} \geq 1\}} \cdot \Phi_{i}^{t} \cdot e^{\frac{-n}{n}}\) to the middle sum (corresponding to Case 2) in [4.1] and subtracting it from the last sum (corresponding to Case 3) transforms [4.1] into

\[
\sum_{i=1}^{n} p_{i}^{t} 1_{\{y_{i}^{t} < 1\}} \sum_{j=1}^{n} \Phi_{j}^{t} e^{\frac{-n(-y_{i}^{t})}{n}} + \sum_{i=1}^{n} p_{i}^{t} 1_{\{y_{i}^{t} \geq 1\}} \sum_{j=1}^{n} \Phi_{j}^{t} e^{\frac{-n}{n}} + \sum_{i=1}^{n} p_{i}^{t} \Phi_{i}^{t} 1_{\{y_{i}^{t} \geq 1\}} e^{\frac{-n}{n}} (e^{\alpha} - 1) + e^{3\alpha} \\
= \sum_{i=1}^{n} p_{i}^{t} \left(1_{\{y_{i}^{t} < 1\}} e^{\frac{-n(-y_{i}^{t})}{n}} + 1_{\{y_{i}^{t} \geq 1\}} e^{\frac{-n}{n}}\right) \sum_{j=1}^{n} \Phi_{j}^{t} + \Phi_{i}^{t} 1_{\{y_{i}^{t} \geq 1\}} e^{\frac{-n}{n}} (e^{\alpha} - 1) + e^{3\alpha} \tag{4.1}
\]

Recall that \(y_{1}^{t} \geq y_{2}^{t} \geq \cdots \geq y_{n}^{t}\), which implies \(\Phi_{1}^{t} \geq \Phi_{2}^{t} \geq \cdots \geq \Phi_{n}^{t} \geq 0\). Thus \(f(i)\) and \(g(i)\) are non-negative and non-increasing in \(i\) and \(\sum_{j=1}^{n} \Phi_{j}^{t} \geq 0\). Consequently, the function \(h(i) = f(i) + g(i) \cdot \sum_{j=1}^{n} \Phi_{j}^{t}\) is non-negative and non-increasing in \(i\). Note that by condition \(\mathcal{P}\) for any \(k \in \mathbb{N}\) it holds that \(\sum_{i=1}^{k} p_{i}^{t} \leq \frac{k}{n}\). Thus we can apply Lemma A.2 which implies \(\sum_{i=1}^{n} p_{i}^{t} \cdot h(i) \leq \sum_{i=1}^{n} \frac{1}{n} \cdot h(i)\). Applying this to the above, rearranging, and splitting \(f(i)\) gives

\[
E[\Phi_{j}^{t+1} | \mathcal{F}^{t}] \leq \frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} < 1\}} e^{\frac{-n(-y_{i}^{t})}{n}} \sum_{j=1}^{n} \Phi_{j}^{t} + \frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} e^{\frac{-n}{n}} \sum_{j=1}^{n} \Phi_{j}^{t} \\
- \frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} \Phi_{i}^{t} e^{\frac{-n}{n}} + \frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} \Phi_{i}^{t} e^{\frac{n}{2}} + e^{3\alpha} \tag{4.2}
\]

Now observe combining the second and third terms above gives

\[
\frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} e^{\frac{-n}{n}} \sum_{j=1}^{n} \Phi_{j}^{t} - \frac{1}{n} \sum_{i=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} \Phi_{i}^{t} e^{\frac{n}{2}} = \frac{1}{n} \cdot e^{\frac{-n}{n}} \sum_{i=1}^{n} \sum_{j=1}^{n} 1_{\{y_{i}^{t} \geq 1\}} \cdot \Phi_{j}^{t} \cdot 1_{(j \neq i)} \\
= \frac{1}{n} \cdot e^{\frac{-n}{n}} \sum_{i=1}^{n} \Phi_{i}^{t} \sum_{j=1}^{n} 1_{\{y_{j}^{t} \geq 1\}} \cdot 1_{(j \neq i)} \\
= \frac{1}{n} \cdot e^{\frac{-n}{n}} \sum_{i=1}^{n} \Phi_{i}^{t} \cdot (|B_{i}^{t}| - 1), \tag{4.3}
\]
where the last line follows since $\Phi^t = e^{\alpha y_f^t} \mathbf{1}_{\{y_f^t \geq 1\}}$.

Now, substituting (4.3) into (4.2), exchanging the first double summation and using the bound $\mathbf{1}_{\{y_f^t \geq 1\}} \leq 1$ on the last sum, and finally grouping terms gives the following

$$E[\Phi^{t+1} | \mathcal{F}^t] \leq \frac{1}{n} \sum_{i=1}^{n} \Phi^t_i \left( \sum_{i=1}^{n} \mathbf{1}_{\{y_f^t < 1\}} e^{-\alpha \frac{\left(\left[-y_f^t\right]+1\right)}{n}} + (\lfloor B_{\geq 1}^t \rfloor - 1) e^{-\frac{\alpha}{n}} + e^{\alpha - \frac{\alpha}{n}} \right) + e^{3\alpha},$$

as claimed. \hfill \Box

Let $\mathcal{G}^t$ be the event that at round $t \geq 0$ either there are at least $n/20$ underloaded bins or there is a an absolute value potential of at least $n/10$. In symbols this is given by

$$\mathcal{G}^t := \{ B_\geq n/20 \} \cup \{ \Delta^t \geq n/10 \}. \quad (4.4)$$

The next lemma provides two estimates on the expected exponential potential $\Phi^{t+1}$ in terms of $\Phi^t$. The first estimate holds for any round and it establishes that the process does not perform worse than One-Choice, meaning that the potential increases by a factor of at most $(1 + \mathcal{O}(\alpha^2/n))$. The second estimate is stronger for rounds where we have a lot of underloaded bins or a large value of the absolute value potential. This stronger estimate states that the potential decreases by a factor of $(1 - \Omega(\alpha/n))$ in those rounds. Note that as we show in Claim B.1, the potential may increase in expectation for certain load configurations, so it seems hard to prove a decrease without looking at several steps.

**Lemma 4.2.** Consider any allocation process satisfying $\mathcal{P}$ and $\mathcal{V}$. There exists a constant $c_1 > 0$ such that for any $0 < \alpha < 1$ and any $t \geq 0$,

$$E \left[ \Phi^{t+1} | \mathcal{F}^t \right] \leq \left( 1 + \frac{c_1 \alpha^2}{n} \right) \cdot \Phi^t + e^{3\alpha}. $$

Further, there exists a constant $c_2 > 0$ such that for any $0 < \alpha < 1/100$ and any $t \geq 0$,

$$E \left[ \Phi^{t+1} | \mathcal{F}^t, \mathcal{G}^t \right] \leq \left( 1 - \frac{c_2 \alpha}{n} \right) \cdot \Phi^t + e^{3\alpha}. $$

**Proof.** Recall that, as before, we fix the labeling chosen by the process in round $t$ such that $x_1^t \geq x_2^t \geq \cdots \geq x_n^t$, thus $x_i^{t+1}$ may not be non-increasing in $i \in [n]$ and $p^t$ being majorized by One-Choice (according to $\mathcal{P}$).

Let $A_i$ be the bracketed term in the expression for $E[\Phi^{t+1} | \mathcal{F}^t]$ in Lemma 4.2, given by

$$A_i = \sum_{j: y_f^j < 1} e^{-\alpha \frac{\left(\left[-y_f^j\right]+1\right)}{n}} + (\lfloor B_{\geq 1}^t \rfloor - 1) e^{-\frac{\alpha}{n}} + e^{\alpha - \frac{\alpha}{n}}. \quad (4.5)$$

Observe that $-\alpha \left(\left[-y_f^j\right]+1\right) \leq -\alpha$ whenever $y_f^j < 1$ and thus

$$A_i \leq \sum_{j: y_f^j < 1} e^{-\frac{\alpha}{n}} + (\lfloor B_{\geq 1}^t \rfloor - 1) e^{-\frac{\alpha}{n}} + e^{\alpha - \frac{\alpha}{n}} = e^{-\frac{\alpha}{n}} \cdot [n - 1 + e^\alpha].$$

Applying the Taylor estimate $e^z \leq 1 + z + z^2$, which holds for any $z \leq 1$, twice gives

$$A_i \leq \left( 1 - \frac{\alpha}{n} + \frac{\alpha^2}{n^2} \right) (n + \alpha + \alpha^2) = n \cdot \left( 1 - \frac{\alpha}{n} + \frac{\alpha^2}{n^2} \right) \left( 1 + \frac{\alpha}{n} + \frac{\alpha^2}{n^2} \right) \leq n \cdot \left( 1 + \frac{c_1 \alpha^2}{n} \right),$$

for some constant $c_1 > 0$. The first statement in the lemma now follows as Lemma 4.1 gives

$$E[\Phi^{t+1} | \mathcal{F}^t] \leq \frac{1}{n} \sum_{i=1}^{n} \Phi^t_i \cdot A_i + e^{3\alpha} \leq \frac{1}{n} \cdot n \left( 1 + \frac{c_1 \alpha^2}{n} \right) \cdot \sum_{i=1}^{n} \Phi^t_i + e^{3\alpha} \leq \left( 1 + \frac{c_1 \alpha^2}{n} \right) \Phi^t + e^{3\alpha}. $$
We shall now show the second statement of the lemma. By splitting sums in \((4.5)\) we have
\[
A_i = \sum_{j \in B^i_-} e^{-\alpha((-y_j^i)^{+1})/n} + \sum_{j:0 \leq y_j^i < 1} e^{-\alpha((-y_j^i)^{+1})/n} + (|B^i_-| - 1) \cdot e^{-\alpha/n} + e^{\alpha - \alpha/n} \\
= \sum_{j \in B^i_-} e^{-\alpha((-y_j^i)^{+1})/n} + (|B^i_-| - 1) \cdot e^{-\alpha/n} + e^{\alpha - \alpha/n} \tag{4.6}
\]
\[
\leq |B^i_-| \cdot e^{-\alpha/n} + (|B^i_-| - 1) \cdot e^{-\alpha/n} + e^{\alpha - \alpha/n} \tag{4.7}
\]
We shall now first assume that \(|B^i_-| \geq n/20\). Recall the bound \(e^x \leq 1 + x + 0.6 \cdot x^2\) which holds for any \(x \leq 1/2\). If \(\alpha < 1/2\), we can apply this bound to \((4.7)\), giving
\[
A_i \leq e^{-\alpha} \cdot \left( |B^i_-| \cdot \left( 1 - \frac{\alpha}{n} + \frac{6\alpha^2}{10n^2} \right) + (|B^i_-| - 1) + 1 + \alpha + \frac{6\alpha^2}{10} \right) \\
\leq \left( 1 - \frac{\alpha}{n} + \frac{6\alpha^2}{10n^2} \right) \cdot n \left( 1 - \frac{\alpha}{20n} + \frac{6\alpha^2}{200n^2} + \frac{\alpha}{n} + \frac{6\alpha^2}{10n} \right) \\
= n \cdot \left( 1 - \frac{\alpha(1 - 12\alpha)}{20n} + \mathcal{O} \left( \frac{\alpha^2}{n^2} \right) \right). \tag{4.8}
\]
We now assume that \(|\Delta_i| \geq n/10\). Observe that by Schur-convexity (see Lemma A.5) and the assumption on \(|\Delta_i|\) we have
\[
\sum_{j \in B^i_-} e^{-\alpha((-y_j^i)^{+1})/n} \leq e^{-\alpha/n} \sum_{j \in B^i_-} e^{\alpha y_j^i/n} \\
\leq e^{-\alpha/n} \cdot \left( (|B^i_-| - 1) \cdot e^{-\alpha/n} + 1 \cdot e^{\alpha/n} \sum_{j \in B^i_-} y_j^i \right) \\
\leq (|B^i_-| - 1) \cdot e^{-\alpha/n} + e^{-\alpha/20},
\]
where we used the fact that \(\sum_{j \in B^i_-} y_j^i = -\frac{1}{2} \Delta_i\). Applying this and the bound \(e^x \leq 1 + x + 0.6 \cdot x^2\), for \(x \leq 1/2\), to \((4.6)\) gives
\[
A_i \leq \left( |B^i_-| - 1 \right) \cdot e^{-\alpha/n} + e^{-\alpha/n} + (|B^i_-| - 1) \cdot e^{-\alpha/n} + e^{\alpha} \\
= (n - 2) \cdot e^{-\alpha/n} + e^{-\alpha/n} + e^{\alpha} \\
\leq (n - 2) \cdot \left( 1 - \frac{\alpha}{n} + \frac{6\alpha^2}{10n^2} \right) + \left( 1 - \frac{\alpha}{20} + \frac{6\alpha^2}{4000} \right) + \left( 1 + \alpha + \frac{6\alpha^2}{10} \right) \\
= n \left( 1 - \frac{\alpha(200 - 2406\alpha)}{4000n} + \mathcal{O} \left( \frac{\alpha^2}{n^2} \right) \right). \tag{4.9}
\]
Thus we see by \((4.8)\) and \((4.9)\) that if \(G^i\) holds and we take \(\alpha < 1/100\) and \(n\) sufficiently large, then there exists some constant \(c_2 > 0\) such that \(A_i \leq n(1 - c_2\alpha/n)\). Thus Lemma 4.1 gives
\[
\mathbb{E} [\Phi^{i+1} | \delta^i, G^i] \leq \frac{1}{n} \sum_{i=1}^n \Phi_i^i \cdot A_i + e^{3\alpha} \leq \frac{1}{n} \cdot n \left( 1 - \frac{c_2\alpha}{n} \right) \cdot \sum_{i=1}^n \Phi_i^i + e^{3\alpha} \leq \left( 1 - \frac{c_2\alpha}{n} \right) \Phi^i + e^{3\alpha},
\]
as claimed. □

The next lemma shows that the event \(G^i\) given by \((4.4)\) holds for sufficiently many rounds.

**Lemma 4.3.** Consider any allocation process satisfying \((\mathcal{P})\) and \((\mathcal{W})\). For every integer \(t_0 \geq 1\), there are at least \(n/40\) rounds \(t \in [t_0, t_0 + n]\) with (i) \(\Delta^i \geq n/10\) or (ii) \(|B^i_-| \geq n/20\).
Proof. We claim that if $\Delta^s \leq n/10$ for some round $s$, then for each round $t \in [s+n/5, s+9n/40]$ we have $|B^s_t| \geq n/20$ (deterministically). The lemma follows from that, since then we either have $\Delta^t \geq n/10$ for all $t \in [t_0, t_0 + n/40]$, or, thanks to the claim there is a $s \in [t_0, t_0 + n/40]$ such that for all $t \in [s+n/5, s+9n/40]$ (this interval has length $n/40$) we have $|B^s_t| \geq n/20$.

To establish the claim, assume we are at any round $s$ where $\Delta^s \leq n/10$. Then at most $n/2$ bins $i$ satisfy $|y^i_s| \geq 1/5$, and in turn at least $n/2$ bins satisfy $|y^i_s| < 1/5$; let us call this latter set of bins $B := \{ i \in [n] : |y^i_s| < 1/5 \}$. In the rounds $[s, s+9n/40]$, we can choose at most $9n/40$ bins in $B$ that are overloaded (at the time when chosen), and then we place exactly one ball into them. Furthermore, in each round $t \in [s, s+9n/40]$ we can turn at most two bins in $B$ which is underloaded at round $t$ and make it overloaded. Hence it follows that at least $n/2 - 2 \cdot 9n/40 = n/20$ of the bins in $B$ are not chosen in the interval $[s, s+9n/40]$. Consequently, these bins must be all underloaded in the interval $[s+n/5, s+9n/40]$. \(\square\)

4.2 Completing the Proof of Theorem 3.1

We now introduce a new potential function $\Phi^t$ which is the product of $\Phi^t$ with two additional terms (and an additive centering term). These multiplying terms have been chosen based on the one step increments in the two statements in Lemma 4.2 and Lemma 4.3. The purpose of this is that using Lemmas 4.2 and 4.3 we can show that $\Phi^t$ is a super-martingale. We then use the super-martingale property to bound the exponential potential at an arbitrary step.

Here, we re-use the definition of the event $G^t$ from (4.4). Now fix an arbitrary round $t_0 \geq 0$. Then, for any $s > t_0$, let $G^s_{t_0}$ be the number of rounds $r \in [t_0, s)$ satisfying $G^r$, and let $B^s_{t_0} := (s - t_0) - G^s_{t_0}$. Further, let the constants $c_1 > 0$ and $c_2 > 0$ be as in Lemma 4.2 let $c_3 := 2e^{3\alpha} \exp(c_2\alpha) > 0$, and then define a sequence by $\Phi^{t_0} := \Phi^{t_0}$, and for any $s > t_0$,

$$\Phi^s := \Phi^s \cdot \exp \left( \frac{c_2\alpha}{n} \cdot G^{s-1}_{t_0} \right) \cdot \exp \left( \frac{-c_1\alpha^2}{n} \cdot B^{s-1}_{t_0} \right) - c_3 \cdot (s - t_0).$$ (4.10)

The next lemma proves that the sequence $\Phi^s$, $s \geq t_0$, forms a super-martingale:

**Lemma 4.4.** Let $0 < \alpha < 1/100$ be an arbitrary but fixed constant, and $t_0 \geq 0$ be an arbitrary integer. Then, for any $s \in [t_0, t_0 + n]$ we have

$$\mathbb{E}[\Phi^{s+1} | \mathcal{F}^s] \leq \Phi^s.$$

**Proof.** First, using the definition $\Phi^s$ from (4.10), we rewrite $\mathbb{E}[\Phi^{s+1} | \mathcal{F}^s]$ to give

$$\mathbb{E}[\Phi^{s+1} | \mathcal{F}^s] = \mathbb{E}[\Phi^{s+1} | \mathcal{F}^s] \cdot \exp \left( \frac{c_2\alpha}{n} \cdot G^s_{t_0} \right) \cdot \exp \left( \frac{-c_1\alpha^2}{n} \cdot B^s_{t_0} \right) - c_3 \cdot (s + 1 - t_0)$$

$$= \mathbb{E}[\Phi^{s+1} | \mathcal{F}^s] \cdot \exp \left( \frac{\alpha}{n} \cdot (c_2 \cdot 1 G^s - c_1 \alpha \cdot (1 - 1 G^s)) \right) \cdot \exp \left( \frac{c_2\alpha}{n} \cdot G^{s-1}_{t_0} \right) \cdot \exp \left( \frac{-c_1\alpha^2}{n} \cdot B^{s-1}_{t_0} \right)$$

$$- c_3 - c_3 \cdot (s - t_0).$$

We claim that it suffices to prove

$$\mathbb{E}[\Phi^{s+1} | \mathcal{F}^s] \cdot \exp \left( \frac{\alpha}{n} \cdot (c_2 \cdot 1 G^s - c_1 \alpha \cdot (1 - 1 G^s)) \right) \leq \Phi^s + c_3 \cdot \exp(-c_2\alpha).$$ (4.11)
Indeed, observe that $G_{t_0}^{s-1} \leq s - t_0 \leq n$, and so assuming \((4.11)\) holds we have

$$
\mathbb{E}[\tilde{\Phi}^{s+1} | \tilde{s}^s]
\leq (\Phi^s + c_3 \cdot \exp(-c_2\alpha)) \cdot \exp\left(\frac{c_2\alpha}{n} \cdot G_{t_0}^{s-1}\right) \cdot \exp\left(-\frac{c_1\alpha^2}{n} \cdot B_{t_0}^{s-1}\right) - c_3 - c_3 \cdot (s - t_0)
\leq \Phi^s.
$$

To show \((4.11)\), we consider two cases based on whether $G^s$ holds.

**Case 1** [$G^s$ holds]. By Lemma 4.2 (first statement) we have

$$
\mathbb{E}[\Phi^{s+1} | \tilde{s}^s, G^s] \leq \Phi^s \cdot \left(1 - \frac{c_2\alpha}{n}\right) + e^{3\alpha} \leq \Phi^s \cdot \exp\left(-\frac{c_2\alpha}{n}\right) + e^{3\alpha}.
$$

Hence, if $G^s$ holds then the left hand side of \((4.11)\) is equal to

$$
\mathbb{E}[\Phi^{s+1} | \tilde{s}^s, G^s] \cdot \exp\left(\frac{\alpha}{n} \cdot c_2\right) \leq \Phi^s \cdot \exp\left(-\frac{c_2\alpha}{n}\right) + e^{3\alpha} \cdot \exp\left(\frac{\alpha}{n} \cdot c_2\right)
\leq \Phi^s + 2e^{3\alpha}
= \Phi^s + c_3 \cdot \exp(-c_2\alpha),
$$

where the last line holds by definition of $c_3 = 2e^{3\alpha} \exp(c_2\alpha)$.

**Case 2** [$G^s$ does not hold]. Lemma 4.2 (second statement) gives the unconditional bound

$$
\mathbb{E}[\Phi^{s+1} | \tilde{s}^s, \neg G^s] \leq \Phi^s \cdot \left(1 + \frac{c_1\alpha^2}{n}\right) + e^{3\alpha} \leq \Phi^s \cdot \exp\left(\frac{c_1\alpha^2}{n}\right) + e^{3\alpha}.
$$

Thus, if $G^s$ does not hold the left hand side of \((4.11)\) is at most

$$
\mathbb{E}[\Phi^{s+1} | \tilde{s}^s, \neg G^s] \cdot \exp\left(\frac{\alpha}{n} \cdot (-c_1\alpha)\right) \leq \Phi^s + e^{3\alpha} \leq \Phi^s + c_3 \cdot \exp(-c_2\alpha),
$$

which establishes \((4.11)\) and the proof is complete. \(\square\)

Combining Lemma 4.3, which shows that a constant fraction of rounds satisfy $G^s$, with Lemma 4.4 establishes a multiplicative drop of $\mathbb{E}[\Phi^s]$ (unless it is already linear). Thus $\mathbb{E}[\Phi^m] = \mathcal{O}(n)$, which implies $\text{Gap}(m) = \mathcal{O}(\log n)$. This is formalized in the proof below.

**Theorem 3.1 (restated).** There exists a universal constant $C > 0$ such that for any allocation process satisfying conditions $\mathcal{P}$ and $\mathcal{W}$ at each round, and for any $m \geq 1$, we have

$$
\Pr[\text{Gap}(m) \leq C \log n] \geq 1 - n^{-2}.
$$

**Proof.** For any integer $t_0 \geq 1$, first consider rounds $[t_0, t_0 + n]$. We will now fix the constant $\alpha := \min\{1/101, 1/20 \cdot c_2/c_1\}$ in the exponential potential function $\Phi^t$ (thus this is also fixed in $\Phi^t$). By Lemma 4.4 $\Phi$ forms a super-martingale over $[t_0, t_0 + n]$, and thus

$$
\mathbb{E}\left[\tilde{\Phi}^{t_0+n} \mid \tilde{s}^{t_0}\right] \leq \Phi^{t_0} = \Phi^{t_0},
$$

which implies

$$
\mathbb{E}\left[\Phi^{t_0+n} \cdot \exp\left(\frac{c_2\alpha}{n} \cdot G_{t_0}^{t_0+n-1}\right) \cdot \exp\left(-\frac{c_1\alpha^2}{n} \cdot B_{t_0}^{t_0+n-1}\right) - c_3 \cdot n \mid \tilde{s}^{t_0}\right] \leq \Phi^{t_0},
$$
Rearranging this, and using that by Lemma 4.3 $G_{t_0}^{t_0 + n - 1} \geq n/40$ holds deterministically, we obtain for any $t_0 \geq 1$
\[
E \left[ \Phi^{t_0 + n} \mid \mathcal{F}^{t_0} \right] \leq (\Phi^{t_0} + c_3 \cdot n) \cdot \exp \left( -c_2 \alpha \cdot \frac{1}{40} + c_1 \alpha^2 \cdot \frac{39}{40} \right),
\]
and now using $\alpha = \min\{1/101, (1/40) \cdot c_2/c_1\}$ and defining $c_4 := c_2/40^2$ yields
\[
E \left[ \Phi^{t_0 + n} \mid \mathcal{F}^{t_0} \right] \leq (\Phi^{t_0} + c_3 \cdot n) \cdot \exp (-c_4 \alpha) = \Phi^{t_0} \cdot \exp (-c_4 \alpha) + c_3 \exp (-c_4 \alpha) \cdot n.
\]
It now follows by the second statement in Lemma A.6 with $a := \exp (-c_4 \alpha) < 1$ and $b := c_3 \exp (-c_4 \alpha) \cdot n$ that for any integer $k \geq 1$,
\[
E \left[ \Phi^{n \cdot k} \right] \leq \Phi^0 \cdot \exp (-c_4 \alpha \cdot k) + \frac{c_3 \exp (-c_4 \alpha) \cdot n}{1 - \exp (-c_4 \alpha)} \leq c_5 \cdot n,
\]
for some constant $c_5 > 0$ as $\Phi^0 \leq n$ holds deterministically.

Hence for any number of rounds $t = k \cdot n + r$, where $k \geq 0$ and $1 \leq r < n$, we use the first statement iteratively to conclude that
\[
E \left[ \Phi^{n \cdot k + r} \right] = E \left[ E \left[ \Phi^{n \cdot k + r} \mid \mathcal{F}^{n \cdot k} \right] \right] 
\leq E \left[ \Phi^{n \cdot k} \right] \cdot \left( 1 + \frac{c_1 \alpha^2}{n} \right)^r \cdot n \cdot \left( 1 + \frac{c_1 \alpha^2}{n} \right)^n \cdot \exp (c_3 \alpha^2) 
\leq c_6 \cdot n \cdot \exp (c_1 \alpha^2) + n \cdot \exp (c_1 \alpha^2) \cdot \exp (c_3 \alpha^2) \leq c_6 \cdot n,
\]
for some constant $c_6 > 0$. Hence for any $m \geq 1$, by Markov’s inequality,
\[
\Pr \left[ \Phi^m \leq c_6 \cdot n^3 \right] \geq 1 - n^{-2}.
\]
Since $\Phi^m \leq c_6 \cdot n^3$ implies $\text{Gap}(m) = O(\log n)$, the proof is complete.

4.3 Proof of Proposition 3.9

Since Biased-Packing is not a filling process our general gap bound does not apply, thus we now give a short and basic proof of the gap bound for this process here.

Proposition 3.9 (restited). For the Biased-Packing process, for any $m \geq 1$,
\[
E \left[ \Delta^m \right] \leq 10n^2,
\]
and hence,
\[
\Pr \left[ \text{Gap}(m) \leq 10n^3 \right] \geq 1 - n^{-1}.
\]
Proof. We will analyze the change of the absolute value potential over an arbitrary step $t$.

The key observation is that when allocating to an underloaded bin $i \in [n]$ with $y^j_i < 0$, that bin contributes at most $-[-y^j_i] + 3$ to the absolute value potential. In addition, the average changes by $([-y^j_i] + 1)/n$. As a result, each overloaded bin contributes $-([-y^j_i] + 1)/n$ and each underloaded bin contributes $([-y^j_i] + 1)/n$. Since there is always at least one overloaded bin, the aggregate change can be upper bounded by
\[
\Delta^{t+1} - \Delta^t \leq -[-y^j_i] + 3 - \frac{[-y^j_i] + 1}{n} + (n - 1) \cdot \frac{[-y^j_i] + 1}{n} \leq \frac{y^j_i}{n} + 4.
\]
Hence, the expected change of the absolute value potential is given by

\[ E[\Delta^{t+1} - \Delta^t | x^t] \leq \sum_{i:y_i^t > 0} p_i \cdot 1 + \sum_{i:y_i^t < 0} p_i \cdot \left(\frac{y_i^t}{n} + 4\right) \leq -\frac{\Delta^t}{2n^2} + 5. \]

By induction, we can show that \( E[\Delta^t] \leq 10n^2 \),

\[ E[\Delta^{t+1}] = E[E[\Delta^{t+1} | \Delta^t]] \leq E[\Delta^t] \cdot \left(1 - \frac{1}{2n^2}\right) + 5 \leq 10n^2 - \frac{10n^2}{2n^2} + 5 = 10n^2. \]

The final part of the result now follows from an application of Markov’s inequality. \( \square \)

## 5 Unfolding General Filling Processes

In this section, we prove our results on (general) unfoldings of filling processes, though first we will recall the definition of the unfolding of a process from Page 9.

Let \( x^t \) be the load vector of a filling process \( P \), and \( \widehat{x}^t \) be the load vector of the unfolding of \( P \) called \( U = U(P) \). Initialize \( x^0 := \widehat{x}^0 \) as the all-zero vector, corresponding to the empty load configuration. For every round \( t \geq 1 \), where \( P \) has allocated \( W^{t-1} \) balls before, we create atomic allocations \( A(t) := \{W^{t-1} + 1, \ldots, W^t\} \), where \( W^t = W^{t-1} + \min\{\lceil -y_i^t \rceil + 1, 1\} \) for process \( U \), such that for each \( s \in A(t) \) a single ball is allocated, and we have \( x^{t+1} := \widehat{x}^{W^{t+1}} \), i.e., the load distribution of \( P \) after round \( t + 1 \) corresponds to load distribution of \( U \) after atomic allocation \( W^{t+1} \geq t + 1 \).

We now show that our notion of “unfolding” can be applied to capture the CACHING process.

**Lemma 3.7 (repeated).** There is a process \( P \) satisfying conditions [P] and [W] such that for a suitable unfolding \( U = U(P) \), the process \( U \) is an instance of CACHING.

**Proof.** As in the definition of unfolding, we denote the load vector of \( P \) after round \( t \) by \( x^t \), and the load vector of a suitable unfolding \( U(P) \) after the \( s \)-th atomic allocation by \( \widehat{x}^s \). We also denote the corresponding normalized load vectors by \( \widehat{y}^s \) respectively.

We will construct by induction, a coupling between a suitable filling process \( P \), satisfying [W] and [P] at each round, and an unfolding \( U(P) \) which follows the distribution of CACHING. That is for every round \( t \geq 0 \) of \( P \), there exists a (unique) atomic allocation \( s = a(t) \geq t \) in \( U(P) \), such that \( x^t = \widehat{x}^{a(t)} \), and \( U(P) \) is an instance of CACHING.

Assume that for a suitable unfolding of the process \( P \), the load configuration of \( P \) after round \( t \) equals the load configuration of \( U(P) \) after atomic allocation \( s = a(t) \), i.e., \( x^t = \widehat{x}^{a(t)} \). In case the cache is empty (which happens only at the first round \( s = 0 \) ), CACHING will sample a uniform bin \( i \) (which satisfies [P]). If the cache is not empty, CACHING will take as bin \( i \) the least loaded of the bin in the cache and a uniformly chosen bin. This produces a distribution vector that is majorized by ONE-CHOICE (thus satisfies [P] again). Thus we may couple the two instances such that process \( P \) samples the same bin \( i \) in round \( t \) and atomic allocation \( a(t) \), respectively. We continue with a case distinction concerning the load of bin \( i \) at round \( t \):

**Case 1** [The bin \( i \) is overloaded, i.e., \( y_i^t = \widehat{y}_i^{a(t)} > 0 \)]. Then CACHING and \( P \) both place one ball into bin \( i \), satisfying [W]. Further, \( P \) proceeds to the next round and \( U(P) \) proceeds to the next atomic allocation, which means that the coupling is extended.

**Case 2** [The bin \( i \) is underloaded, i.e., \( y_i^t = \widehat{y}_i^{a(t)} < 0 \)]. Then we can deduce by definition of CACHING that it will place the next \( \lceil -\widehat{y}_i^{a(t)} \rceil + 1 \) balls in some way that it deterministically satisfies the following conditions: (i) the first \( \lceil -\widehat{y}_i^{a(t)} \rceil \) balls are placed into bins which have a normalized load \( < 0 \) at the atomic allocation \( a(t) \), (ii) one ball is placed into a bin with normalized load \( < 1 \) at the atomic allocation \( a(t) \). This follows since bin \( i \) gets stored in the cache and at each atomic allocation \( j = W^{t-1} + 1, \ldots, W^t \) the process has access to a cached
bin with normalized load at most $y_{t_i}^{a(t)} + j - 1$. This satisfies $W$, so we can continue the coupling.

We have thus constructed a process $P$, such that some unfolding $U = U(P)$ of $P$ is an instance CACHING.

We now prove the general gap bound for the unfolding of the processes.

**Lemma 3.8 (repeated).** Fix any constant $c > 0$. Then for any filling process $P$ satisfying $W$ and $P$, there is a constant $C = C(c) > 0$ such that for any number of atomic allocations $m \geq 1$, with probability at least $1 - n^{-2}$, any unfolding $U = U(P)$ satisfies

$$\left| \{ t \in [m] : \text{Gap}_U(t) \leq C \cdot \log n \} \right| \geq n^{-c} \cdot m \log m.$$  

**Proof.** We will re-use the constants $\alpha \in (0, 1)$ and $c_0 > 0$ defined in the proof of Theorem 3.1. We now define

$$B := \left| \{ t \in [1, m] : \Phi^t \geq c_0 \cdot n^{6+c} \} \right|,$$

which is the number of “bad” rounds of the filling process $P$. Let $w^t := W^t + 1 - W^t$ denote the number of balls allocated in round $t$. We continue with a case distinction for each round $t$ whether $t \in B$ holds.

- **Case 1** [$t \notin B$]. By definition, for a round $t \notin B$ we have $\Phi^t < c_0 n^{6+c}$. Further, $\Phi^t < c_0 n^{6+c}$ implies $\text{Gap}_P(t) < \frac{10}{\alpha} \cdot \log n$, for sufficiently large $n$. Now let $a(t), a(t) + 1, \ldots, a(t) + w^t - 1, w^t := [y_{t_i}^1] + 1$ be the atomic allocations in $U(P)$ corresponding to round $t$ in $P$. Since all allocations of $U(P)$ are to bins with normalized load at most 1 before the allocation, we conclude $\text{Gap}_{U(P)}(s) \leq \max \{ \text{Gap}_P(t), 2 \} < \frac{10}{\alpha} \cdot \log n$ for all $s \in [a(t), a(t) + w^t - 1]$.

- **Case 2** [$t \in B$]. We will use that for any $0 < \alpha < 1$ and $t \geq 0$ we have

$$\Delta^t \leq 2n \cdot \left( \frac{1}{\alpha} \log \Phi^t + 1 \right).$$

To see this, observe that $\sum_{i \in B_1} y_i^t = -\sum_{i \in B_1} y_i^t$ and thus

$$\Delta^t \leq 2 \sum_{i \in B_1^+} y_i^t \leq 2 \sum_{i \in B_1^+} y_i^t \cdot 1_{y_i^t \geq 2} + 2n. \quad (5.1)$$

Now, note that since $\Phi^t = \sum_{i \in [n]} y_i^t \exp (\alpha \cdot y_i^t)$, if $\Phi^t \leq \lambda$ then $y_i^t \leq \frac{1}{\alpha} \cdot \log \lambda$ for all $i \in [n]$ with $y_i^t \geq 2$. Thus by (5.1) we have $\Delta^t \leq 2n \cdot (1/\alpha) \log \Phi^t + 2n$ as claimed.

So for a round $t \in B$, we have

$$w^t \leq \Delta^t + 1 \leq \frac{2n}{\alpha} \log \Phi^t + 2n + 1 \leq c_n \log \Phi^t, \quad (5.2)$$

which holds deterministically for some constant $c_n > 0$. Again, every such round $t \in B$ of $P$ corresponds to the atomic allocations $a(t), a(t) + 1, \ldots, a(t) + w^t - 1$ in $U(P)$, and we will (optimistically) assume that the gap in all those rounds is large, i.e., at least $\frac{10}{\alpha} \cdot \log n$.

By the above case distinction and (5.2), we can upper bound the number of rounds $s$ in $[1, m]$ of $U(P)$ where $\text{Gap}_{U(P)}(s) < \frac{10}{\alpha} \cdot \log n$ does not hold as follows:

$$\left| \left\{ s \in [1, m] : \text{Gap}_{U(P)}(s) \geq \frac{10}{\alpha} \cdot \log n \right\} \right| \leq \sum_{t=1}^m 1_{t \in B} \cdot w^t \leq c_n n \cdot \sum_{t=1}^m 1_{t \in B} \cdot \log \Phi^t. \quad (5.3)$$
Next define the sum of the exponential potential function over rounds 1 to \( m \) as

\[
\Phi := \sum_{t=1}^{m} \Phi^t.
\]

Then from the proof of Theorem 3.1 equation (4.13), there is a constant \( c_6 > 0 \) such that

\[
E[\Phi] = \sum_{t=1}^{m} E[\Phi^t] \leq m \cdot c_6 \cdot n.
\]

By Markov’s inequality,

\[
\Pr[\Phi \leq m \cdot c_6 \cdot n^3] \geq 1 - n^{-2}. \tag{5.4}
\]

Note that conditional on the above event occurring, the following bound holds deterministically:

\[
|B| \leq \frac{mc_6n^3}{c_6n^{3+c}} \leq m \cdot n^{-3-c}.
\]

If \( B \) is empty we are done by (5.3). So we can assume that \( |B| \geq 1 \) and apply the Log-sum inequality Lemma A.1, with

\[
a_t = 1 \quad \text{and} \quad b_t = \Phi^t,
\]

to the sum over \( B \) in (5.3), which gives us

\[
\sum_{t=1}^{m} 1_{t \in B} \log \Phi^t = \sum_{t \in B} \log \Phi^t \leq \left( \sum_{t \in B} 1 \right) \log \left( \frac{\sum_{t \in B} \Phi^t}{\sum_{t \in B} 1} \right) \leq |B| \log \left( \frac{\Phi}{|B|} \right). \tag{5.5}
\]

Now, if the event \( \Phi \leq m \cdot c_6 \cdot n^3 \) occurs, then by (5.3) and (5.5) we have

\[
\left\{ s \in [1, m]: \text{Gap}_{U(P)}(s) \geq \frac{10}{\alpha} \cdot \log n \right\} \leq c_an \cdot |B| \cdot \log \left( \frac{\Phi}{|B|} \right) \leq c_an \cdot (m \cdot n^{-3-c}) \cdot \log \left( m \cdot c_6 \cdot n^3 \right) \leq c'_an \cdot m \cdot n^{-2-c} \cdot (\log m + \log n) \leq m \cdot n^{-c} \cdot \log m,
\]

where the third inequality is for some constant \( c'_a \) depending on \( \alpha \) and the last inequality holds since \( \alpha > 0 \) is a small but fixed constant thus \( c'_a \) is constant. Since the inequality holds for any unfolding of \( P \), once the event in (5.4) occurs, we obtain the result. \( \square \)

### 6 Lower Bounds on the Gap

In this section we shall prove several lower bounds for filling processes. In Section 6.1, we prove an \( \Omega \left( \frac{\log n}{\log \log n} \right) \) lower bound for the PACKING and TIGHT-PACKING processes for \( m = O(n) \) rounds. In Section 6.2, for the PACKING process, we prove a tight \( \Omega(\log n) \) lower bound for any \( m = \Omega(n \log n) \) (see Table 1 for a concise overview of our lower and upper bounds).

#### 6.1 Lower Bound for Uniform Processes

We first prove a general lower bound which holds for any process that picks bins for allocation uniformly and can then increment the load of that chosen bin arbitrarily. Since PACKING and TIGHT-PACKING choose a uniform bin for allocation at each round, the result below immediately yields a gap bound of \( \Omega \left( \frac{\log n}{\log \log n} \right) \) for these processes for \( m = O(n) \) rounds.

**Lemma 6.1.** Consider any allocation process, which at each round \( t \geq 0 \), picks a bin \( i^t \) uniformly. Furthermore, assume that at any round \( t \geq 0 \) the allocation process increments the load of bin \( i^t \) by some function \( f^t \geq 1 \), which may depend on \( S^t \) and \( i^t \). Then, there is a constant \( d_1 > 0 \) such that

\[
\Pr \left[ \text{Gap} \left( \frac{n}{2} \right) \geq d_1 \cdot \frac{\log n}{\log \log n} \right] \geq 1 - o(1).
\]
Proof. Recall the fact (see, e.g., [23]) that in a One-Choice process with \( n/2 \) balls into \( n \) bins, with probability at least \( 1 - o(1) \) there is a bin \( i \in [n] \) which will be chosen at least \( \kappa \cdot \frac{\log n}{\log \log n} \) times during the first \( n/2 \) allocations, where \( \kappa > 0 \) is some constant. Hence in our process

\[
x_i^{n/2} \geq \left( \kappa \cdot \frac{\log n}{\log \log n} \right) \cdot 1,
\]

for some \( i \in [n] \) w.h.p. as at least one ball is allocated at each round.

Let us define \( f^* := \max_{1 \leq t \leq n/2} f_t \) to be the largest number of balls allocated in one round. Then, clearly, \( W_{n/2} \leq \left( \frac{n}{2} \right) \cdot f^* \). Furthermore, there must be at least one bin \( j \in [n] \) which receives \( f^* \) balls in one of the first \( n/2 \) rounds. Thus for any such bin,

\[
x_j^{n/2} \geq f^*,
\]

and therefore the gap is lower bounded by

\[
\text{Gap}(n/2) \geq \max \left\{ x_i^{n/2}, x_j^{n/2} \right\} - \frac{W_{n/2}}{n} \geq \max \left\{ \kappa \cdot \frac{\log n}{\log \log n}, f^* \right\} - \frac{f^*}{2}.
\]

If \( f^* \geq \kappa \cdot \frac{\log n}{\log \log n} \), then the lower bound is \( \frac{1}{2} f^* \geq \frac{\kappa}{2} \cdot \frac{\log n}{\log \log n} \). Otherwise, \( f^* < \kappa \cdot \frac{\log n}{\log \log n} \), and the lower bound is at least \( \kappa \cdot \frac{\log n}{\log \log n} - \frac{\kappa}{2} \cdot \frac{\log n}{\log \log n} = \frac{\kappa}{2} \cdot \frac{\log n}{\log \log n} \).

### 6.2 An Improved Lower Bound for Packing

In this section we prove a lower bound that is tight up to a multiplicative constant for Packing when \( m = \Omega(n \log n) \). The result is proven using the following two technical Lemmas that will also be useful when proving the upper bound in Theorem 3.2, our sample efficiency result.

The first lemma concerns the absolute value potential \( \Delta^t \).

**Lemma 6.2.** There exists a universal constant \( \tilde{c} > 0 \) such that for any allocation process satisfying conditions \( P \) and \( W \) at each round, and any \( t \geq 0 \), we have \( \mathbb{E} \left[ \Delta^t \right] \leq \tilde{c} n \).

**Proof.** Recall that for the constant \( \alpha := \min \{1/101, 1/20 \cdot c_2/c_1\} \),

\[
\Phi^t = \sum_{i: y_t^i \geq 2} e^{\alpha y_t^i}.
\]

Hence, using that \( e^z \geq 1 + z \) for any \( z \),

\[
\Phi^t \geq \sum_{i: y_t^i \geq 2} (1 + \alpha y_t^i) \geq \sum_{i: y_t^i \geq 2} \alpha y_t^i \geq \sum_{i: y_t^i \geq 2} \alpha (y_t^i - 2) \geq \alpha \cdot \left( \frac{\Delta^t}{2} - 2n \right). \tag{6.1}
\]

By (4.13) for some constant \( c_6 > 0 \) and for any \( t \geq 0 \),

\[
\mathbb{E} \left[ \Phi^t \right] \leq c_6 \cdot n.
\]

Using (6.1), this implies that

\[
\mathbb{E} \left[ \Delta^t \right] \leq \frac{c_6}{\alpha} \cdot \mathbb{E} \left[ \Phi^t \right] + 4n \leq \frac{2c_6}{\alpha} \cdot n + 4n =: \tilde{c} n, \tag{6.2}
\]

with the constant \( \tilde{c} := \frac{2c_6}{\alpha} + 4 \).

For the second lemma, recall that \( W^t \) is the number of balls allocated up to round \( t \).
Lemma 6.3. Let $\tilde{c}$ be the universal constant from Lemma 6.2. Then for any allocation process satisfying conditions $\mathcal{W}$ and $\mathcal{P}$ with a uniform probability vector at each round, and any $m \geq t_0 \geq 0$ we have
\[
\mathbb{E}[W^m - W^{t_0}] \leq (\tilde{c} + 2) \cdot (m - t_0).
\]

Proof. For any $t_0 \geq 0$, we fix $\tilde{W}^{t_0} := 0$, and for any $t > t_0$ we let
\[
\tilde{W}^t := W^t - W^{t_0} - 2 \cdot (t - t_0) - \frac{1}{n} \cdot \sum_{s=t_0+1}^{t} \Delta^s. \tag{6.3}
\]
We shall show that $\tilde{W}^t$ is a supermartingale. Taking expectations over one step for $t > 0$,
\[
\mathbb{E} \left[ \tilde{W}^t \mid \mathcal{F}^{t-1} \right] = W^{t-1} - W^{t_0} + \sum_{i:y_i^{t-1} \geq 0} p_i + \sum_{i:y_i^{t-1} < 0} p_i \cdot (1 + \lceil -y_i^{t-1} \rceil) - 2 \cdot (t - t_0) - \frac{1}{n} \cdot \sum_{s=t_0+1}^{t} \Delta^s
\leq W^{t-1} - W^{t_0} + |B_i^{t-1}| \cdot \frac{1}{n} + 2 \cdot |B_i^{-t-1}| \cdot \frac{1}{n} + \frac{\Delta^{t-1}/n}{2} - 2 \cdot (t - t_0) - \frac{1}{n} \cdot \sum_{s=t_0+1}^{t} \Delta^s
\leq W^{t-1} - W^{t_0} + \frac{\Delta^{t-1}}{n} - 2 \cdot (t - t_0) - \frac{1}{n} \cdot \sum_{s=t_0+1}^{t-1} \Delta^s
= W^{t-1} - W^{t_0} - 2 \cdot (t - t_0 - 1) - \frac{1}{n} \cdot \sum_{s=t_0+1}^{t-1} \Delta^s
= \tilde{W}^{t-1},
\]
where in (a) we used that $p_i = 1/n$ and $\sum_{i:y_i^{t-1} < 0} -y_i^{t-1} \leq \sum_{i:y_i^{t-1} < 0} (-y_i^{t-1} + 1) \leq \Delta^{t-1}/n + |B_i^{-t-1}|$. This proves that $\tilde{W}^t$ is a supermartingale. Thus, since $\tilde{W}^{t_0} = 0$, for any $m \geq t_0$ we have
\[
\mathbb{E} \left[ \tilde{W}^m \right] \leq \tilde{W}^{t_0} = 0.
\]
Finally, recalling that $\mathbb{E} \left[ \Delta^t \right] \leq \tilde{c} n$ for any $t \geq 0$ by Lemma 6.2 we have
\[
\mathbb{E} \left[ W^m - W^{t_0} \right] \leq \frac{1}{n} \cdot \mathbb{E} \left[ \sum_{s=t_0+1}^{m} \Delta^s \right] + 2 \cdot (m - t_0) \leq \tilde{c} + 2 \cdot (m - t_0),
\]
by (6.3) for the universal constant $\tilde{c} > 0$ given by Lemma 6.2.

We are now ready to prove the main result in this Section.

Theorem 3.5 (rephrased). For the packing process, there exists a constant $\kappa > 0$ such that for any $m \geq \kappa n \log n$,
\[
\mathbb{P} \left[ \text{Gap}(m) \geq \sqrt{\frac{\kappa}{20}} \cdot \log n \right] \geq \frac{1}{2}.
\]

Proof. Recall that for any $m \geq t_0 \geq 0$ we have $\mathbb{E} \left[ W^m - W^{t_0} \right] \leq (\tilde{c} + 2) \cdot (m - t_0)$ by Lemma 6.3. Since $W^m \geq W^{t_0}$ holds deterministically, we can apply Markov’s inequality to give
\[
\mathbb{P} \left[ W^m \geq W^{t_0} + 4 \cdot (\tilde{c} + 2) \cdot (m - t_0) \right] \geq \frac{3}{4}. \tag{6.4}
\]
Recall that $\mathbb{E} \left[ \Delta^{t_0} \right] \leq \tilde{c} n$ for any $t_0 \geq 0$ by Lemma 6.2. Then, using Markov’s inequality
\[
\mathbb{P} \left[ \Delta^{t_0} \geq 8\tilde{c} n \right] \geq \frac{7}{8}. \tag{6.5}
\]
Fix $t_0 := m - \kappa n \log n \geq 0$, for some constant $\kappa > 0$ to be defined shortly, and define the set

\[ B := \{ i \in [n] : y_{i1}^{\text{to}} \geq -128 \cdot \hat{c} \} . \]

Note that any $i \in B$ satisfies $x_{i1}^{\text{to}} \geq \frac{W_{i0}}{n} - 128 \hat{c}$. Further, if \( \{ \Delta_{\text{to}} \leq 8 \cdot \hat{c} n \} \) holds, then $|B| \geq (15/16)n$ holds deterministically. By a coupling with the One-Choice process with $\tilde{m} := \kappa n \log n$ balls and $n$ bins, with probability at least $1 - o(1)$ there is a bin that is sampled at least $\frac{\sqrt{\kappa}}{10} \cdot \log n$ times (e.g., [23]). By symmetry, with probability $15/16$, this maximally chosen bin is in $B$. Since each time a bin is sampled by Packing, it gets at least one ball, thus

\[
\Pr \left[ \bigcup_{i \in [n]} \left\{ x_{i1}^{\text{to}} \geq \frac{W_{i0}}{n} + \frac{\sqrt{\kappa}}{10} \cdot \log n - 128 \hat{c} \right\} \cap \left\{ \Delta_{\text{to}} \leq 8 \cdot \hat{c} n \right\} \right] \geq 1 - o(1) - \frac{1}{8} - \frac{1}{16} \geq \frac{3}{4}.
\]

(6.6)

Assuming that $\bigcup_{i \in [n]} \left\{ x_{i1}^{\text{to}} \geq \frac{W_{i0}}{n} + \frac{\sqrt{\kappa}}{10} \cdot \log n - 128 \hat{c} \right\}$ and $\{ W_{\text{m}} \leq W_{\text{to}} + 4 \cdot (\hat{c} + 2) \cdot (m - t_0) \}$ hold, by choosing $\kappa := \left( \frac{1}{100(\hat{c} + 2)} \right)^2$, there exists some $i \in [n]$ such that

\[
y_{i1}^{\text{to}} \geq \frac{W_{i0}}{n} + \frac{\sqrt{\kappa}}{10} \cdot \log n - 128 \hat{c} - \frac{W_{\text{m}}}{n} \geq \frac{\sqrt{\kappa}}{10} \cdot \log n - \kappa \cdot 4 \cdot (\hat{c} + 2) \cdot \log n - 128 \hat{c} \geq \frac{\sqrt{\kappa}}{20} \cdot \log n.
\]

Taking the union bound over (6.4) and (6.6),

\[
\Pr \left[ \text{Gap}(m) \geq \frac{\sqrt{\kappa}}{20} \cdot \log n \right] \geq \frac{3}{4} - \frac{1}{4} = \frac{1}{2}.
\]

\[ \Box \]

\section{Sample Efficiency of Filling Processes}

Recall that $W^t := \sum_{i \in [n]} x_i^t$ and $S^t$ are the total number of balls allocated and bins sampled by round $t$ respectively. Thus $S^t = t$ and $W^t \geq t$ for Packing. The same holds for any process satisfying $\mathcal{P}$ and $\mathcal{W}$ assuming (i) that we can directly sample a bin $i$ according to the probability vector $p$, and (ii) we do not count the allocation of balls into bins other than $i$ as an additional sample (see Tight-Packing). Recall that the sample efficiency is given by

\[
\eta^t = \frac{W^t}{S^t}.
\]

Since assumption (i) above is quite unnatural, we restrict ourselves to processes satisfying $\mathcal{W}$ and $\mathcal{P}$ with uniform probability vectors and prove that they are more sample-efficient than One-Choice.

\textbf{Theorem 3.2 (restated).} There exist universal constants $c, C > 0$ such that for any process satisfying $\mathcal{W}$ and $\mathcal{P}$ with a uniform probability vector at each round, and for any $m \geq 2$ we have

\[
1 + c \leq \mathbb{E}[\eta^m] \leq C.
\]

The empirical results of Fig. 6 strongly support this, suggesting that the sample efficiency of Packing is around $3/2$ on average.

\textbf{Proof of Theorem 3.2.} Since in each round of a process with a uniform probability vector $p^t = (1/n, \ldots, 1/n)$ satisfying $\mathcal{W}$ samples exactly one random bin we have $S^t = t$ deterministically, thus $\eta^t = W^t/t$. Now observe that

\[
\mathbb{E} \left[ W^{t+1} - W^t \mid \mathcal{F}^t \right] = \sum_{i : y_i^t \geq 0} 1 \cdot \frac{1}{n} + \sum_{i : y_i^t < 0} (1 + [y_i^t]) \cdot \frac{1}{n} = 1 + \sum_{i : y_i^t < 0} [-y_i^t] \cdot \frac{1}{n}.
\]

(7.1)
Since $\Delta' = \sum_{i=1}^{n} |y'_i|$ and $\sum_{i=1}^{n} y'_i = 0$, we have $E[W^t + 1 - W^t | \{\delta\}] \geq 1 + \frac{\Delta'}{2n}$ by (7.1). Thus,

$$E[W^t + 1 - W^t | \delta] \cdot 1_{\{\Delta' \geq n/10\}} \geq \left(1 + \frac{1}{20}\right) \cdot 1_{\{\Delta' \geq n/10\}}. \tag{7.2}$$

Recall that $B^t$ is the number of underloaded bins at time $t$. Thus by (7.1) we have

$$E[W^t + 1 - W^t | \delta] \cdot 1_{\{B^t \geq n/20\}} \geq \left(1 + \frac{n}{20} \cdot \frac{1}{n}\right) 1_{\{B^t \geq n/20\}} = \left(1 + \frac{1}{20}\right) 1_{\{B^t \geq n/20\}}. \tag{7.3}$$

For any $t_0 \geq 1$, $t \in [t_0, t_0 + n]$, define $A$ to be the (random) set of times $t \in [t_0, t_0 + n]$ where the event $E_t = \{\Delta' \geq n/10\} \cup \{|B^t| \geq n/2\}$ holds. By (7.2) and (7.3) we have

$$E[W^t + 1 - W^t | \delta] 1_{E_t} \geq 1 + 1/20. \tag{7.4}$$

Now, by Lemma 4.3 for any $t_0 \geq 1$ we have $P[A \geq n/40] = 1$ and so

$$E[W^{t_0 + n} - W^{t_0}] \geq E\left[\frac{n}{40} \cdot \left(1 + \frac{1}{20}\right) + \frac{39n}{40} \right] = n \left(1 + \frac{1}{800}\right). \tag{7.4}$$

Since the bound from (7.4) holds for any $t_0 \geq 1$ the result follows for any $t > n$ (more details given below) however we must first consider the case $2 \leq t \leq n$ separately.

Observe that in the first round we place one ball. Then until $n$ balls have been placed we place two balls if we sample an underloaded bin and this is the most we can place in any round.

We have little control how these are placed but certainly for any round $r \leq \lfloor n/3 \rfloor$ there are at least $n - 1 - 2 \cdot (\lfloor n/3 \rfloor - 1) \geq \lfloor n/3 \rfloor$ underloaded (empty) bins when we sample a bin. It follows that for any $r \leq \lfloor n/3 \rfloor$ the number of underloaded bins samples (excluding the first) in the first $r$ rounds stochastically dominates a Bin($r - 1, 1/3$) random variable, which has median at least $\lfloor (r - 1)/3 \rfloor$. Thus, with probability at least 1/2, at least $\lfloor (r - 1)/3 \rfloor$ of the first $r$ rounds contribute two balls. This is not greater than 0 for $r \leq 6$, however for $2 \leq r \leq 6$ at most $1 + 2 \cdot 6 = 13$ bins are occupied. Thus for any $2 \leq r \leq 6$ two ball are assigned in $r - 1 \geq 1$ of the first $r$ rounds (all rounds but the first) with probability at least $1 - 5 \cdot (13/n) \geq 1/2$ by the union bound, since we assume throughout that $n$ is sufficiently large. Thus for any $2 \leq r \leq \lfloor n/3 \rfloor$ we have

$$E[W^r] \geq r + \frac{1}{2} \max\{\lfloor (r - 1)/3 \rfloor, 1\} \geq r \cdot \left(1 + \frac{1}{12}\right)$$

If we assume (pessimistically) that only one ball is allocated at any round $t > \lfloor n/3 \rfloor$, then for any $t \leq n$ we have

$$E[W^t] \geq E[W_{\min\{t, \lfloor n/3 \rfloor\}}] + \min\{0, t - \lfloor n/3 \rfloor\} \geq t \cdot \left(1 + \frac{1}{50}\right).$$

Hence for any $2 \leq t \leq n$ we have $E[\eta^t] \geq E[W^t] / t > 1 + 1/50$. Also for any $t > n$ we have

$$E[\eta^t] \geq \frac{1}{t} \cdot \left[\frac{(t-1)/n}{t} \cdot \sum_{i=1}^{(t-1)/n} E[W^{i+n+1} - W^{(i-1)n+1}] + \left(t - \left\lfloor \frac{t-1}{n} \right\rfloor \cdot n\right)\right] \geq \frac{1}{t} \cdot \left(t + \frac{1}{800} \cdot \left(t - \left\lfloor \frac{t-1}{n} \right\rfloor \cdot n\right)\right) \geq 1 + \frac{1}{1600}.$$
by (7.4). Thus taking \( c = 1 + \frac{1}{1600} \) gives the lower bound on \( E[\eta^t] \).

For the upper bound, by Lemma 6.3, for any \( m \geq t_0 \geq 0 \) we have

\[
E \left[ W^m - W^{t_0} \middle| \mathcal{F}^{t_0} \right] \leq (\tilde{c} + 2) \cdot (m - t_0),
\]

for some universal constant \( \tilde{c} > 0 \). We now choose \( m = t \) and \( t_0 = 0 \), and using \( E[W^0] = 0 \), we conclude

\[
E[W^t] \leq (\tilde{c} + 2) \cdot t.
\]

Using this, and since for any process satisfying \( P \) and \( Y \) \( S^t = t \) holds deterministically, we conclude that

\[
E[\eta^t] = E \left[ \frac{W^t}{S^t} \right] = \frac{E[W^t]}{E[S^t]} \leq \frac{(\tilde{c} + 2) \cdot t}{t} := C,
\]

for the constant \( C = \tilde{c} + 2 \).

\[\square\]

8 Experimental Results

In this section, we present some empirical results for the PACKING, TIGHT-PACKING and CACHING processes (Fig. 5 and Table 2) and compare their load with that of a \((1 + \beta)\) process with \( \beta = 0.5 \), a QUANTILE\((1/2)\) process, and the TWO-CHOICE process.

![Figure 5: Average Gap vs. \( n \in \{10^3, 10^4, 5 \cdot 10^4, 10^5\} \) for the experimental setup of Table 2](image)

![Figure 6: Sample efficiency for the PACKING process versus the number of rounds over the number of bins \( n \) for \( n \in \{10^3, 10^4, 10^5\} \). The sample efficiency seems to converge to 1.5.](image)

\caption{Summary of observed gaps for $n \in \{10^3, 10^4, 10^5\}$ bins and $m = 1000 \cdot n$ number of balls, for 100 repetitions. The observed gaps are in bold and next to that is the \% of runs where this was observed.}
\end{table}

9 Conclusions

In this work, we introduced a new balanced allocation process, PACKING, which selects at each step a random bin, and if the bin is overloaded, allocates a single ball; otherwise it “fills” the underloaded bin with balls up until it becomes overloaded. In contrast to ONE-CHOICE, this process achieves w.h.p. an $O(\log n)$ gap at an arbitrary round (Theorem 3.1). We proved that this upper bound is tight for any sufficiently large $m$ (Theorem 3.5). In contrast to TWO-CHOICE, $(1 + \beta)$ and QUANTILE(1/2), we showed that PACKING is more sample-efficient than ONE-CHOICE.

For the analysis of the upper bound of PACKING, we introduced a general framework, which also captures the CACHING process by Mitzenmacher, Prabhakar and Shah [19] and TIGHT-PACKING. For all processes falling into this framework, we proved an $O(\log n)$ upper bound on the gap (Theorem 3.1). For those with uniform probability vectors, we showed that they are sample-efficient (Theorem 3.2).

There are several possible extensions to this work. One is to explore stronger versions of the conditions on the probability vector which might imply $o(\log n)$ gap bounds. Experimental results in Fig. 5 suggest that for CACHING, the $o(\log n)$ gap bound (known for $m = n$ [19]) extends to the heavily-loaded case.

At the opposite end, one might investigate probability vectors with weaker guarantees. In Section 3.4 we showed that for BIASED-PACKING, a variant of the PACKING process that uses a probability vector that majorizes One-Choice, the gap is at most poly($n$), i.e., still independent of $m$. This demonstrates the “power of filling” in balanced allocations.
Acknowledgments

We thank David Croydon and Martin Krejca for some helpful discussions.

A Analysis and Concentration Inequalities

Lemma A.1 (Log-Sum Inequality [4, Theorem 2.7.1]). For any natural number \( n \geq 1 \), let \( a_1, \ldots, a_n \) and \( b_1, \ldots, b_n \) be nonnegative real numbers and \( a := \sum_{i=1}^{n} a_i \) and \( b := \sum_{i=1}^{n} b_i \). Then
\[
\sum_{i=1}^{n} a_i \log \left( \frac{a_i}{b_i} \right) \geq n \log \left( \frac{a}{b} \right)
\]
or equivalently
\[
\sum_{i=1}^{n} a_i \log \left( \frac{b_i}{a_i} \right) \leq n \log \left( \frac{b}{a} \right).
\]

The following lemma is similar to [10, Lemma A.1.]

Lemma A.2. Let \( (a_k)_{k=1}^{n} \), \( (b_k)_{k=1}^{n} \) be non-negative and \( (c_k)_{k=1}^{n} \) be non-negative and non-increasing. If \( \sum_{k=1}^{n} a_k \leq \sum_{k=1}^{n} b_k \) holds for all \( 1 \leq i \leq n \) then,
\[
\sum_{k=1}^{n} a_k \cdot c_k \leq \sum_{k=1}^{n} b_k \cdot c_k. \tag{A.1}
\]

Proof. We shall prove (A.1) holds by induction on \( n \geq 1 \). The base case \( n = 1 \) follows immediately from the fact that \( a_1 \leq b_1 \) and \( c_1 \geq 0 \). Thus we assume \( \sum_{k=1}^{n-1} a_k \cdot c_k \leq \sum_{k=1}^{n-1} b_k \cdot c_k \) holds for all sequences \( (a_k)_{k=1}^{n-1}, (b_k)_{k=1}^{n-1} \) and \( (c_k)_{k=1}^{n-1} \) satisfying the conditions of the lemma.

For the inductive step, suppose we are given sequences \( (a_k)_{k=1}^{n}, (b_k)_{k=1}^{n} \) and \( (c_k)_{k=1}^{n} \) satisfying the conditions of the lemma. If \( c_2 = 0 \) then, since \( (c_k)_{k=1}^{n} \) is non-increasing and non-negative, \( c_k = 0 \) for all \( k \geq 2 \). Thus as \( a_1 \leq b_1 \) and \( c_1 \geq 0 \) by the precondition of the lemma, we conclude
\[
\sum_{k=1}^{n} a_k \cdot c_k = a_1 \cdot c_1 \leq b_1 \cdot c_1 = \sum_{k=1}^{n} b_k \cdot c_k.
\]

We now treat the case \( c_2 > 0 \). Define the non-negative sequences \( (a'_k)_{k=1}^{n-1} \) and \( (b'_k)_{k=1}^{n-1} \) as follows:
\[
\begin{align*}
\bullet \ a'_1 &= \frac{a_1}{c_2} \cdot a_1 + a_2 \quad \text{and} \quad a'_k = a_{k+1} \quad \text{for} \quad 2 \leq k \leq n - 1, \\
\bullet \ b'_1 &= \frac{a_1}{c_2} \cdot b_1 + b_2 \quad \text{and} \quad b'_k = b_{k+1} \quad \text{for} \quad 2 \leq k \leq n - 1,
\end{align*}
\]

Then as the inequalities \( c_1 \geq c_2, a_1 \leq b_1 \) and \( \sum_{i=1}^{n} a_k \leq \sum_{i=1}^{n} b_k \) hold by assumption, we have
\[
\sum_{k=1}^{n-1} a'_k = \left( \frac{c_1}{c_2} - 1 \right) a_1 + \sum_{k=1}^{n-1} a_k \leq \left( \frac{c_1}{c_2} - 1 \right) b_1 + \sum_{k=1}^{n-1} b_k = \sum_{k=1}^{n-1} b'_k.
\]

Thus if we also let \( (c'_k)_{k=1}^{n-1} = (c_{k+1})_{k=1}^{n-1} \), which is positive and non-increasing, then
\[
\sum_{k=1}^{n-1} a'_k \cdot c'_k \leq \sum_{k=1}^{n-1} b'_k \cdot c'_k,
\]
by the inductive hypothesis. However
\[
\sum_{k=1}^{n-1} a'_k \cdot c'_k = \left( \frac{c_1}{c_2} \cdot a_1 + a_2 \right) c_2 + \sum_{k=2}^{n-1} a_{k+1} \cdot c_{k+1} = \sum_{k=1}^{n} a_k \cdot c_k,
\]
and likewise \( \sum_{k=1}^{n-1} b'_k \cdot c'_k = \sum_{k=1}^{n} b_k \cdot c_k \). The result follows.

For completeness, we define Schur-convexity (see [17]) and state two basic results:

Definition A.3. A function \( f : \mathbb{R}^n \to \mathbb{R} \) is Schur-convex if for any non-decreasing \( x, y \in \mathbb{R}^n \), if \( x \) majorizes \( y \) then \( f(x) \geq f(y) \). A function \( f \) is Schur-concave if \( -f \) is Schur-convex.
Lemma A.4. Let \( g : \mathbb{R} \to \mathbb{R} \) be a convex (resp. concave) function. Then \( g(x_1, \ldots, x_n) := \sum_{i=1}^{n} g(x_i) \) is Schur-convex (resp. Schur-concave).

Lemma A.5. For any \( \alpha > 0 \), for any \( \beta \in \mathbb{R} \) and any \( \Delta \in \mathbb{R} \), consider \( f(x_1, x_2, \ldots, x_k) = \sum_{j=1}^{k} \exp(-\alpha x_j) \), where \( \sum_{j=1}^{k} x_j \geq \Delta \) and \( x_j \geq \beta \) for all \( 1 \leq j \leq k \). Then,

\[
 f(x_1, x_2, \ldots, x_k) \leq (k - 1) \cdot \exp(-\alpha \cdot \beta) + 1 \cdot \exp(-\alpha \cdot (\Delta - (k - 1) \cdot \beta)).
\]

Proof. Note that by Lemma A.4, it follows that \( f(x_1, \ldots, x_n) \) is Schur-concave, as \( f(x_1, \ldots, x_n) = \sum_{i=1}^{n} g(x_i) \) and \( g(z) = e^{-\alpha z} \) is concave for \( \alpha > 0 \). As a consequence, the function attains its maximum if the values \( (x_1, x_2, \ldots, x_k) \) are as “spread out” as possible, i.e., if any prefix sum of the values ordered non-increasingly is as large as possible. \( \square \)

Lemma A.6. Consider any sequence \((z_i)_{i \in \mathbb{N}}\) such that, for some \( a > 0 \) and \( b > 0 \), for every \( i \geq 1 \),

\[
 z_i \leq z_{i-1} \cdot a + b.
\]

Then for every \( i \in \mathbb{N} \),

\[
 z_i \leq z_0 \cdot a^i + b \cdot \sum_{j=0}^{i-1} a^j.
\]

Further, if \( a < 1 \), then

\[
 z_i \leq z_0 \cdot a^i + \frac{b}{1-a}.
\]

Proof. We will prove the first claim by induction. For \( i = 0 \), \( z_0 \leq z_0 \). Assume the induction hypothesis holds for some \( i \geq 0 \), then since \( a > 0 \),

\[
 z_{i+1} \leq z_i \cdot a + b \leq (z_0 \cdot a^i + b \cdot \sum_{j=0}^{i-1} a^j) \cdot a + b = z_0 \cdot a^{i+1} + b \cdot \sum_{j=0}^{i} a^j.
\]

Hence, the first claim follows. The second part of the claim is immediate, since for \( a \in (0, 1) \), \( \sum_{j=0}^{\infty} a^j = \frac{1}{1-a} \). \( \square \)

B  Counterexample for the Exponential Potential Function

In this section, we present a configuration for which the exponential potential function \( \Phi \) (such as the one defined in Section 4), increases by a multiplicative factor in expectation, in a round \( t \) where the “good event” \( G_t \) does not hold.

Claim B.1. For any constant \( \alpha > 0 \) and for sufficiently large \( n \), consider the (normalized) load configuration,

\[
 y^t = (\sqrt{n}, \underbrace{0, \ldots, 0}_{n-\sqrt{n}-1 \; bins}, -1, \ldots, -1). 
\]

Then, for the PACKING process, the potential function \( \Phi^t := \sum_{i, y_i^t \geq 0} e^\alpha y_i^t \) will increase in expectation, i.e.,

\[
 E[\Phi^{t+1} | \widetilde{S}^t] \geq \Phi^t \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right).
\]

Proof. Consider the contribution of bin \( i = 1 \), with \( y_1^t = \sqrt{n} \).

\[
 E[\Phi_1^{t+1} | \widetilde{S}^t] = e^\alpha \sqrt{n} \cdot \left(1 + \frac{1}{n} \cdot (e^\alpha - \alpha/n - 1) + \frac{n - \sqrt{n} - 1}{n} \cdot (e^{-\alpha/n} - 1) + \frac{\sqrt{n}}{n} \cdot (e^{-2\alpha/n} - 1)\right).
\]
Now using a Taylor estimate $e^z \geq 1 + z + 0.3z^2$ for $z \geq -1.5$,

$$E[\Phi_{t+1} | \tilde{\mathbf{y}}^t] \geq e^{\alpha \sqrt{n}} \cdot \left(1 + \frac{1}{n} \cdot \left(\alpha - \frac{\alpha}{n} + 0.3 \cdot \left(\alpha - \frac{\alpha}{n}\right)^2\right) + \frac{n - \sqrt{n} - 1}{n} \cdot \left(- \frac{\alpha}{n} + 0.3 \cdot \frac{\alpha^2}{n^2}\right)\right)$$

$$+ \frac{\sqrt{n}}{n} \cdot \left(- \frac{2\alpha}{n} + 1.2 \cdot \frac{\alpha^2}{n^2}\right)$$

$$= e^{\alpha \sqrt{n}} \cdot \left(1 + \frac{\alpha + 0.3 \cdot \alpha^2}{n} - \frac{\alpha}{n} + o(n^{-1})\right)$$

$$= e^{\alpha \sqrt{n}} \cdot \left(1 + 0.3 \cdot \frac{\alpha^2}{n} + o(n^{-1})\right)$$

$$\geq e^{\alpha \sqrt{n}} \cdot \left(1 + 0.2 \cdot \frac{\alpha^2}{n}\right).$$

At round $t$, the contribution of the rest of the bins is at most $n$, i.e., $\sum_{i>1,y_i^t=0} \Phi_i^t \leq n$. Note that since $\alpha$ is a constant for sufficiently large $n$, we have $n \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right) < 0.1 \cdot \alpha^2 \cdot e^{\alpha \sqrt{n}}$. Hence,

$$E[\Phi_{t+1} | \tilde{\mathbf{y}}^t] \geq e^{\alpha \sqrt{n}} \cdot \left(1 + 0.2 \cdot \frac{\alpha^2}{n}\right) = e^{\alpha \sqrt{n}} \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right) + 0.1 \cdot \frac{\alpha^2}{n} \cdot e^{\alpha \sqrt{n}}$$

$$\geq \Phi_t^t \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right) + n \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right)$$

$$\geq \Phi_t^t \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right) + \left(\sum_{i>1,y_i^t=0} \Phi_i^t\right) \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right)$$

$$= \Phi_t^t \cdot \left(1 + 0.1 \cdot \frac{\alpha^2}{n}\right). \quad \square$$
