CLASSIFICATION OF \((q,q)\)-BIPROJECTIVE APN FUNCTIONS

FARUK GÖLOĞLU

Abstract. In this paper, we classify \((q,q)\)-biprojective almost perfect nonlinear (APN) functions over \(\mathbb{L} \times \mathbb{L}\) under the natural left and right action of \(\text{GL}(2, \mathbb{L})\) where \(\mathbb{L}\) is a finite field of characteristic 2. This shows in particular that the only quadratic APN functions (up to CCZ-equivalence) over \(\mathbb{L} \times \mathbb{L}\) that satisfy the so-called subfield property are the Gold functions and the function \(\kappa : F_{64} \rightarrow F_{64}\) which is the only known APN function that is equivalent to a permutation over \(\mathbb{L} \times \mathbb{L}\) up to CCZ-equivalence. The \(\kappa\)-function was introduced in (Browning, Dillon, McQuistan, and Wolfe, 2010). Deciding whether there exist other quadratic APN functions (possibly CCZ-equivalent to permutations) that satisfy subfield property or equivalently, generalizing \(\kappa\) to higher dimensions was an open problem listed for instance in (Carlet, 2015) as one of the interesting open problems on cryptographic functions.

1. Introduction

Almost perfect nonlinear (APN) functions are cryptographically important functions over a vector space over the finite field of order two that provides the best resistance against differential cryptanalysis. Arguably the most important open problem on APN functions is the question on the existence of APN permutations over even dimensional vector spaces. There are no APN permutations over \(F_2^4\) and \(F_2^8\) [30]. Existence of an APN permutation over \(F_2^6\) was shown in [8]. The function is CCZ-equivalent (see Sections 2 and 3 for the definitions of the concepts that are used in Introduction) to the quadratic function \(\kappa : F_{2^6} \rightarrow F_{2^6}\). Note that we will view the finite field \(F_{2^l}\) as a vector space \(F_2^{2l}\) and also as \(F_{2^l} \times F_{2^l}\). When \(\kappa\) is viewed as a polynomial over the finite field \(F_{2^6}\) it falls into the class of Dembowski-Ostrom polynomials that satisfy the subfield property introduced in [8]. These polynomial functions when viewed as functions over \(F_{2^l} \times F_{2^l}\) form the class of \((q,q)\)-biprojective functions. Of course a natural question that arises is to determine whether Dembowski-Ostrom polynomials that satisfy the subfield property (or, equivalently, the class of \((q,q)\)-biprojective functions) contain APN functions that are CCZ-equivalent to permutations for \(l > 3\). The question is viewed as an important problem. For instance it was included by Carlet in a list of interesting research questions regarding cryptologic functions [15, Section 3.7] as an important subproblem of the major problem of deciding whether there exists an APN permutation when \(l > 3\). The problem also appeared in [21, Problem 15]. In this paper, we solve this problem.

Theorem 1.1. Let \(q = 2^k\), \(r = 2^l\), \(\mathbb{L} = F_{2^l}\) with \(0 < k < l\) and \(F : \mathbb{L} \times \mathbb{L} \rightarrow \mathbb{L} \times \mathbb{L}\) be a \((q,q)\)-biprojective function. Then \(F\) is APN if and only if \(\gcd(k,l) = 1\), and

\[
\begin{align*}
(i) \text{ } l \text{ is even and } F &\approx_{\mathbb{L}} G_{q+1} \text{ or } F \approx_{\mathbb{L}} G_{q+r}, \text{ or} \\
(ii) \text{ } l \text{ is odd, } k \text{ is odd, and } F &\approx_{\mathbb{L}} G_{q+1}, \text{ or} \\
(iii) \text{ } l \text{ is odd, } k \text{ is even, and } F &\approx_{\mathbb{L}} G_{q+r}, \text{ or} \\
(iv) \text{ } l = 3 \text{ and } F &\approx_{\mathbb{L}} \kappa.
\end{align*}
\]

We have the following clarifications for the statement of the theorem.

- The equivalence relation $\approx_L$ is introduced by the action of $\text{GL}(2, \mathbb{L}) \times \text{GL}(2, \mathbb{L})$ which is a finer notion of equivalence than that of CCZ-equivalence. Thus our results imply CCZ-equivalence results.
- The biprojective maps $G_s : \mathbb{L} \times \mathbb{L} \to \mathbb{L} \times \mathbb{L}$ with $s \in \{q + 1, q + r\}$ are the so-called Gold maps $X \mapsto X^s$ in the univariate notation with a suitable identification of the vector spaces.
- The Gold maps $G_{2(2j+1)}$ over $\mathbb{L} \times \mathbb{L}$ are APN whenever $\gcd(j, 2l) = 1$ by [20]. APN Gold maps over $\mathbb{L} \times \mathbb{L}$ are not CCZ-equivalent to permutations by [28]. Thus, a $(q, q')$-biprojective APN function $F$ over $\mathbb{L} \times \mathbb{L}$ is CCZ-equivalent to a permutation if and only if $l = 3$ and $F \approx_L \kappa$.
- The special case $k = 1$ was solved in [17] using results from [39, 38, 27]. Thus, our theorem generalizes the main results of [17, 39, 38, 27].
- Another idea to attack the problem is to identify a class of functions that includes $\kappa$ when $l = 3$ and also are CCZ-equivalent to permutations for larger $l$. This is the case of the so-called butterfly construction [41] which requires $l$ to be odd. In [12, 11], butterflies were shown not to be APN when $l > 3$. We will show in Remark 5.4 that a subcase of our Proposition 5.2 (which is a subcase of the main theorem) strictly generalizes the butterfly construction. Thus, our theorem also generalizes the main results of [12, 11].
- The proof is based on three concepts:
  - zeroes of projective polynomials [6],
  - properties of Dillon-Dobbertin difference sets [19], and
  - recent classification of fractional projective permutations over finite fields [23].
- The proof avoids the use of Weil bound and is purely combinatorial.

The natural actions of the groups $\text{GL}(2, \mathbb{L}) \times \text{GL}(2, \mathbb{L})$ (left and right application of non-singular $\mathbb{L}$-linear transformations) and $(\mathbb{L}^x \times \mathbb{L}^x) \times \text{GL}(2, \mathbb{L})$ (scaling on both components and right application of non-singular $\mathbb{L}$-linear transformations) on bivariate vectorial Boolean functions of type

$$F : \mathbb{L} \times \mathbb{L} \to \mathbb{L} \times \mathbb{L}$$

and the action of $\mathbb{L}^x \times \text{GL}(2, \mathbb{L})$ on bivariate vectorial Boolean functions of type

$$f : \mathbb{L} \times \mathbb{L} \to \mathbb{L}$$

are important for this paper. The set of $(q, q')$-biprojective functions is fixed (setwise) by the action $(\mathbb{L}^x \times \mathbb{L}^x) \times \text{GL}(2, \mathbb{L})$ (actually, $(q, q')$-biprojectivity is defined in such a way to accommodate this property). This and other niceties introduced by $\text{PGL}(2, \mathbb{L})$ on $q$-projective functions allows one to prove the rather straightforward fact [22, Lemma 3.6] that whether these functions are APN can be checked in a simple way using parametrization from $\mathbb{P}^1(\mathbb{L})$ instead of $\mathbb{L} \times \mathbb{L}$ which also hints why we have many such families. A method to find new biprojective APN families was given as well in [22, Lemma 4.2] along with two biprojective APN families. These group actions and biprojectivity were instrumental in giving a method (in joint works with Lukas Kölsh) to check equivalences between biprojective APN functions [24, Theorem 3] and isotopisms between biprojective semifields [25, Theorem 5.10], which allowed us to solve the equivalence problem for all known biprojective APN families and, in the semifields case, generalizing a result of Albert [2] to give a solution to a 60-year old problem of Hughes [31] on determining the autotopism group of Knuth semifields [26]. The first ever family of commutative semifields of odd order that contains an exponential number of non-isotopic semifields [25, Corollary 6.4], and a family containing an exponential number of inequivalent APN functions [24].
Theorem 5] were given recently using this method. In the case of APN functions, Kaspers and Zhou were the first [34] to prove such a result with a different method. They showed that the Taniguchi family [42], which is also \((q, q')\)-biprojective, contains an exponential number of inequivalent APN functions. In the \((q, q)\)-biprojective case, even the larger action \(\text{GL}(2, \mathbb{L}) \times \text{GL}(2, \mathbb{L})\) fixes the set of \((q, q)\)-biprojective functions (setwise). This fact can be seen as the main reason that the classification in this paper is possible which we will heavily exploit (see Section 3 ff.) together with the above mentioned properties introduced by these classical groups on \((q, q)\)-biprojective functions. Note that these are natural and well-known group actions which were used previously on biprojective semifields [4, 5].

Of course, the study of bivariate functions and semifields (not necessarily biprojective) has a long history. In the case of semifields, the bivariate idea dates back almost a century to Dickson [18], Hughes and Kleinfeld [32] and Knuth [36]. For the APN functions, the initial work on bivariate functions was by Carlet [13] who found the first biprojective APN family, and then Zhou and Pott [44] introduced another family of biprojective APN functions as well as a family of commutative semifields that contains a quadratic number of inequivalent members. Carlet, then introduced [14] a method to find bivariate (but not necessarily biprojective) APN functions from his previous biprojective family. Further work on biprojective APN functions includes the family of Taniguchi [42], and quite recently the papers [40, 10] which derive both biprojective and non-biprojective APN families from the family of [22] (or by extending it). The method of [14] was further investigated in [9]. Further work that do not involve constructions of bivariate functions but study their important properties include [3, 35, 37, 33].

In Section 2 we will explain the notions related to vectorial Boolean functions, including the definitions of biprojective functions, Dembowski-Ostrom polynomials and APN functions that we mentioned in Introduction. In Section 2, we will explain the various actions we introduced above (and more) on vectorial functions and the corresponding equivalence relations including \(\approx_{\text{CCZ}}\) and \(\approx_{L}\) mentioned above. We also determine the equivalence classes of one of these actions which will give us a representative set of biprojective functions which will reduce the problem of classification of all biprojective functions to the problem of classification of functions in the representative set. Section 4 contains results required in the proof of the main theorem related to zeroes of projective polynomials, Dillon-Dobbertin difference sets and the recent classification of fractional projective permutations over finite fields. Finally, in Section 5, we prove our main theorem.

2. Preliminaries

Let \(F : \mathbb{F}_2^n \rightarrow \mathbb{F}_2^n\) be a vectorial Boolean function. A function \(F\) is said to be almost perfect nonlinear (APN) if

\[
F(x) + F(x + a) = b
\]

has zero or two solutions for every \((a, b) \in \mathbb{F}_2^n \setminus \{0\} \times \mathbb{F}_2^n\). Every vectorial Boolean function \(F : \mathbb{F}_2^n \rightarrow \mathbb{F}_2^n\) can be written as an evaluation function of a polynomial over \(\mathbb{F}_{2^n}[X]\) with (polynomial) degree at most \(2^n - 1\), i.e., \(F : X \mapsto F(X)\) where

\[
F(X) = \sum_{i=0}^{2^n-1} A_i X^i.
\]
We will not make distinction between functions and their polynomial representations. The **algebraic degree** of a vectorial Boolean function is defined to be

\[ \text{deg}_{\text{alg}}(F) = \max \{\text{wt}_2(i) : A_i \neq 0\}, \]

where \( \text{wt}_2 \) denotes the weight of base-2 representation of an integer. When we say **quadratic**, **affine** or **linear**, we refer to this notion of degree. We will need the usual **polynomial degree** as well which will be denoted by

\[ \text{deg}(F) = \max \{i : A_i \neq 0\} \]
as usual. The polynomials in \( \mathbb{F}_{2^n}[X] \) that correspond to **affine** functions are

\[ M(X) = \sum_{0 \leq i \leq n-1} C_i X^{2^i} + D. \]

If \( D = 0 \), they are called **linear** functions and are \( \mathbb{F}_2 \)-linear vector-space endomorphisms of \( \mathbb{F}_{2^n} \) when viewed as a \( \mathbb{F}_2 \)-vector space. As polynomials in \( \mathbb{F}_{2^n}[X] \), they are known as **linearized polynomials**.

We are particularly interested in the class of quadratic polynomials in \( \mathbb{F}_2[X] \) viewed as a \( \mathbb{F}_2 \)-vector space. As polynomials in \( \mathbb{F}_2[X] \), they are called **linearized polynomials**.

The subclass of the above class of polynomials that contain only the non-affine parts is known as **Dembowski-Ostrom (DO)** polynomials, i.e.,

\[ D(X) = \sum_{0 \leq i \neq j \leq n-1} B_{ij} X^{2^i+2^j}. \]

When \( n = 2l \), a further subclass of DO polynomials is important. The class of polynomials

\[ R(X) = AX^{q+1} + BX^{2^{l}(q+1)} + CX^{q+2^l} + DX^{2^l q+1}, \]

where \( q = 2^k \) with \( 0 < k < l \), satisfying the **subfield property**,

\[ R(aX) = a^{q+1} R(X), \quad \text{for all } a \in \mathbb{F}_{2^l}, \]

contains (up to CCZ-equivalence) the only known APN function \( \kappa \) that is CCZ-equivalent to a permutation for even \( n \) (we will describe various notions of equivalences of vectorial Boolean functions further below). Let \( L = \mathbb{F}_{2^l} \). Identifying \( \mathbb{F}_{2^{2l}} = L(\xi) = L\xi + L \cong L \times L \), we can write the above class of functions \( X \mapsto R(X) \) as \( (x,y) \mapsto R(x,y) \) with

\[
R(x,y) = ((a_0 x^{q+1} + b_0 x^q y + c_0 xy^q + d_0 y^{q+1}), (a_1 x^{q+1} + b_1 x^q y + c_1 xy^q + d_1 y^{q+1}))
\]

\[ = (f(x,y), g(x,y)) \]

where \( X = (x\xi + y) \). This motivates the following definition.

**Definition 2.1.** Let \( q = 2^k \) with \( 0 < k < l \).

- Let \( f \in L[x, y] \) be a polynomial of the form

\[ f(x,y) = a_0 x^{q+1} + b_0 x^q y + c_0 xy^q + d_0 y^{q+1}. \]

Then \( f \) is called a **\( q \)-biprojective polynomial**.

- Let \( R : L \times L \to L \times L \) be a function of the form

\[ R : (x,y) \mapsto R(x,y) = (f(x,y), g(x,y)) \]

where \( f \) and \( g \) are \( q \)-biprojective polynomials. Then \( R \) is called a \((q,q)\)-**biprojective function**.
We will use the shorthand notation
\[ f = (a_0, b_0, c_0, d_0)_q, \]
and
\[ R = ((a_0, b_0, c_0, d_0)_q, (a_1, b_1, c_1, d_1)_q) = (f, g). \]

The subfield property can be recognized in this form. For a \((q, q)\)-biprojective map \( F = (f, g), \) one has
\[ (f(cx, cy), g(cx, cy)) = c^{q+1}(f(x), g(y)), \quad \text{for all } c, x, y \in \mathbb{L}. \]

**Remark 2.2.** One can generalize the concept to \((q, q')\)-biprojective functions
\[ F : (x, y) \mapsto F(x, y) = ((a_0, b_0, c_0, d_0)_q, (a_1, b_1, c_1, d_1)_{q'}), \]
where \( q' = 2^{k'} \) (here one allows \( 0 \leq k, k' < l \). These functions satisfy a modified form of the subfield property
\[ (f(cx, cy), g(cx, cy)) = (c^{q+1}f(x), c^{q'+1}g(y)), \quad \text{for all } c, x, y \in \mathbb{L}. \]

In this paper, we are only interested in \((q, q)\)-biprojective functions. See [22, 24] for more on \((q, q')\)-biprojective APN functions and their constructions, equivalences and enumerations.

Define
\[
D_f^q(x, y) = b_0 x^q + c_0 x + d_0 y^q + d_0 y,
\]
\[
D_f^\infty(x, y) = a_0 x^q + a_0 x + c_0 y^q + b_0 y,
\]
\[
D_f^j(x, y) = (a_0x + b_0)x^q + (a_0u^q + c_0)x + (c_0u + d_0)y^q + (b_0u^q + d_0)y,
\]
for \( u \in \mathbb{L}^\times \). The following lemma was proved in [22].

**Lemma 2.3.** Let \( F = (f, g) \) be a \((q, q')\)-biprojective function. Then \( F \) is APN if and only if \( D_f^q(x, y) = 0 = D_f^\infty(x, y) \) has exactly two solutions for each \( u \in \mathbb{P}(\mathbb{L}). \)

2.1. **The trace map and Hilbert’s Theorem 90.** Let \( \mathbb{L} \) be the finite field with \( p^k \) elements, \( q = p^k \) for \( k > 0 \) and let \( \mathbb{D} \subset \mathbb{L} \) of order \( p^\delta \) with \( \delta = \gcd(k, l) \). The **trace map** is defined as
\[
\text{tr}_{\mathbb{L}/\mathbb{D}}(x) = \sum_{j=0}^{l/\delta-1} x^{(p^\delta)^j}.
\]

When \( \mathbb{D} = \mathbb{F}_p \) then we simply write
\[
\text{tr}(x) = \text{tr}_{\mathbb{L}/\mathbb{F}_p}(x).
\]

The following is the finite fields version of Hilbert’s Theorem 90.

**Lemma 2.4** (Hilbert’s Theorem 90). Let \( \gcd(j, l) = 1 \) and \( a \in \mathbb{L} \). Then \( \text{tr}_{\mathbb{L}/\mathbb{D}}(a) = 0 \) if and only if \( a = x^{(p^\delta)^j} - x \) for some \( x \in \mathbb{L} \).

The \( \mathbb{D} \)-linear vector-space endomorphisms of \( \mathbb{L} \) can be written as
\[
L(x) = \sum_{j=0}^{l/\delta-1} a_j x^{(p^\delta)^j}, \quad a_j \in \mathbb{L},
\]
and are called **\( \mathbb{D} \)-linearized polynomials.** Determining kernels of such endomorphisms in \( \mathbb{L} \), especially of the form \( L(x) = ax^q - bx \) and the zeroes of its translates \( L(x) + c \), is important for this paper.
This can simply be done by observing
\[ ax^q - bx = 0 \]
for some nonzero \( r \in \mathbb{L} \) if and only if \( r^{q-1} = b/a \). In that case \( L(rx)/rb = x^q - x \).

Then one can deduce that the zeroes of \( L(x) \) are 0 and \( \epsilon r \) for \( \epsilon \in \mathbb{D} \times \) if such \( r \) exists. Then the case \( L(x) + c \) can be handled using Hilbert’s Theorem 90. The following lemma is relevant and will be needed.

Lemma 2.5. For a prime \( p \),

(i) \( \gcd(p^k - 1, p^l - 1) = p^{\gcd(k,l)} - 1 \).

(ii)

\[
\gcd(p^k + 1, p^l - 1) = \begin{cases} 
1 & \text{if } \frac{l}{\gcd(k,l)} \text{ is odd, and } p = 2, \\
2 & \text{if } \frac{l}{\gcd(k,l)} \text{ is odd, and } p \text{ is odd,} \\
p^{\gcd(k,l)} + 1 & \text{if } \frac{l}{\gcd(k,l)} \text{ is even.}
\end{cases}
\]

2.2. Difference sets with Singer parameters and multisets. Let \( M \) be a multiset whose elements are \( s_i \) with repetition \( d_i \) for \( 1 \leq i \leq r \), denoted by

\[
M = \langle s_1^{d_1}, \ldots, s_r^{d_r} \rangle,
\]

where we write \( \text{mult}_M(s_i) = d_i \). When all \( s_i \) have the same repetition number \( d \), we write \( M = S[d] \), where \( S = \{s_1, \ldots, s_r\} \).

For two multisets \( S, T \) we denote by

\[
S/T = \langle s/t : s \in S, t \in T \rangle
\]

the direct division of two multisets.

A subset \( D \) of cardinality \( k \) of a group \( G \) (written multiplicatively) of order \( v \) is said to be a \((v, k, \lambda)\)-difference set if

\[
D/D = \{1\}^k \cup (G \setminus \{1\})^{[\lambda]}.
\]

We are mostly interested in the cyclic difference sets in the multiplicative group \( \mathbb{L}^\times \) in characteristic 2. The parameters \((2^l - 1, 2^{l-1}, 2^{l-2})\) and \((2^l - 1, 2^{l-1} - 1, 2^{l-2} - 1)\) are called Singer parameters, since they are the parameters of the Singer sets (i.e., hyperplanes of \( \mathbb{L} \)),

\[
\mathcal{H} = \{x \in \mathbb{L} : \text{tr}(x) = 1\},
\]

and \( \mathcal{H} \setminus \{0\} \) where

\[
\mathcal{H} = \{x \in \mathbb{L} : \text{tr}(x) = 0\},
\]

respectively. Dillon-Dobbertin difference sets are another important example of cyclic difference sets with Singer parameters [19] (see Lemmas 4.1, 4.3) which we will use frequently in this paper.

2.3. Equivalences of vectorial Boolean functions. Let \( F : \mathbb{F} \to \mathbb{F} \) be a vectorial Boolean function and \( \mathbb{F} = \mathbb{F}_{2^n} \). The widest known notion of equivalence that keeps the APN property invariant is called the CCZ-equivalence [16]. Define the graph of the function \( F \) by

\[
\Gamma_F = \{(x, F(x)) : x \in \mathbb{F}\}.
\]
Then $F$ is said to be CCZ-equivalent to $F'$ if there exists $\mathbb{F}_2$-linear endomorphisms $A, B, C, D$ of $\mathbb{F}$, elements $u, v \in \mathbb{F}$ and a permutation $\pi : \mathbb{F} \to \mathbb{F}$ such that

$$
\begin{pmatrix}
A & B \\
C & D
\end{pmatrix} \begin{pmatrix}
x \\
F(x)
\end{pmatrix} + \begin{pmatrix}
u \\
v
\end{pmatrix} = \begin{pmatrix}
\pi(x) \\
F'(\pi(x))
\end{pmatrix}.
$$

In that case we write $F \approx_{\text{CCZ}} F'$. A narrower notion of equivalence that keeps the algebraic degree of $F$ invariant is called the extended affine (EA) equivalence. We write $F \approx_{\text{EA}} F'$ if

$$A_1 \circ F \circ A_2(x) + A_3(x) = F'(x),$$

for affine maps $A_1, A_2, A_3 : \mathbb{F} \to \mathbb{F}$ with $A_1, A_2$ bijective. It can easily be shown that EA-equivalence is a special case of CCZ-equivalence where one sets $B = 0$. An important theorem for quadratic APN functions is that for two quadratic APN functions $F, G$ we have by a result of Yoshiara [43],

$$F \approx_{\text{EA}} G \iff F \approx_{\text{CCZ}} G.$$

We can restrict the equivalence even more if, for instance, we want to keep the property of being a permutation invariant. The functions $F$ and $F'$ are said to be linearly equivalent if

$$L_1 \circ F \circ L_2 = F',$$

for $L_1, L_2 \in \text{GL}(n, 2)$. Note that this is equivalent to setting $B = C = 0$ and $u = v = 0$ in (2) (when only $B = C = 0$ holds, they are called affinely equivalent). We denote this equivalence by $F \approx_{\text{GL}(n, 2)} F'$. In the following, we will even restrict this equivalence to the case where $L_1, L_2 \in \text{GL}(2, l) < \text{GL}(2l, 2)$ when $n = 2l$ with the obvious motivation that the (left and right) action of $\text{GL}(2, l)$ keeps the $(q, q)$-biprojective property of $F(x, y) = (f(x, y), g(x, y))$ invariant.

### 3. Actions of GL(2, L) and PGL(2, L)

In this section we outline the basics of several actions of $\text{GL}(2, L)$ and $\text{PGL}(2, L)$ on biprojective functions. Most of this section can be considered standard lore. Let

$$\mathcal{V}_{q, L} = \{(a, b, c, d)_q : a, b, c, d \in \mathbb{L}\},$$

be the set of all $q$-biprojective polynomials. Let $f, g \in \mathcal{V}_{q, L}$ be two $q$-biprojective polynomials and

$$F : \mathbb{L} \times \mathbb{L} \to \mathbb{L} \times \mathbb{L}$$

be the associated $(q, q)$-biprojective function. Define $\mathcal{F}_{q, L}$ to be the set of all $(q, q)$-biprojective functions, i.e.,

$$\mathcal{F}_{q, L} = \mathcal{V}_{q, L} \times \mathcal{V}_{q, L}.$$

Let $\mathcal{L}(\mathbb{L})$ be the group of all nonsingular $\mathbb{L}$-linear transformations of $\mathbb{L} \times \mathbb{L}$, i.e.,

$$\text{GL}(2, L) \cong \mathcal{L}(\mathbb{L}) = \{(x, y) \mapsto (tx + uy, vx + wy) : t, u, v, w \in \mathbb{L} \mid tw - uv \neq 0\}.$$

We are mainly interested in the standard action of $\text{GL}(2, L) \times \text{GL}(2, L)$ on $(q, q)$-biprojective functions $F \in \mathcal{F}_{q, L}$. That is

$$F'(x, y) = L_1 \circ F \circ L_2(x, y).$$

This action defines an equivalence relation which we denote by $F' \approx_{\mathcal{L}} F$. Define also the action of the group $\mathbb{L}^\times \times \text{GL}(2, L)$ on $q$-biprojective polynomials $f \in \mathcal{V}_{q, L}$ where $\mathbb{L}^\times < \text{GL}(2, L)$ acts on $f$ by
3.1. Roots of projective polynomials. Let \( q = p^k \), \( \mathbb{D} = \mathbb{F}_{p^k} \), \( L = \mathbb{F}_{p^l} \) where \( \delta = \gcd(k, l) \) and \( f(x) = ax^{q+1} + bx^q + cx + d \)
be a nonzero $q$-projective polynomial. If $a = 0$, then $f$ is an affine polynomial and the set of zeroes of $f$ in $L$, i.e.,

$$Z'_f = \{ x \in L : f(x) = 0 \}$$

satisfies $|Z'_f| \in \{ 0, 1, p^{\delta} \}$. To see that, first observe that scaling, i.e., $f \mapsto \alpha f$ for $\alpha \in L^\times$, the translations $f(x) \mapsto f(x + \beta)$ for $\beta \in L$ and the dilations $f(x) \mapsto f(\gamma x)$ for $\gamma \in L^\times$ keep the number of zeroes of $f$ in $L$ invariant. Then we have only a few options to consider:

- $f = 1$
  has no $L$-zeroes — degenerate case (together with omitted $f = 0$).
- $f \in \{ x, x^q \}$
  has one $L$-zero.
- $f = x^q - cx - d$ where $c \neq 0$.
  We have
  - if $c = A^q - 1 \in (L^\times)^{q - 1}$, then $f$ has
    * $p^{\delta}$ $L$-zeroes if $\text{tr}_{L/D}(d/A^q) = 0$, and
    * no $L$-zeroes if $\text{tr}_{L/D}(d/A^q) \neq 0$; or
  - one $L$-zero if $c \not\in (L^\times)^{q - 1}$, by Hilbert’s Theorem 90.

Now assume $a \neq 0$. We will show that $|Z'_f| \in \{ 0, 1, 2, p^{\delta} + 1 \}$. Assume $f$ has at least one $L$-zero $r \in Z'_f$. Now consider

$$f'(x) = f(x + r) = ax^{q + 1} + b'x^q + c'x.$$

The reciprocal $f''(x) = x^{q+1}f'(1/x)$ is

$$f''(x) = a + b'x + c'x^q,$$

where $\deg f'' < q + 1$. Now $f''$ has one fewer $L$-zeroes than $f'$ (since we punctured the zero of $f'$ at 0) and thus we have

$$|Z''_f| + 1 = |Z'_f| = |Z'_f| \in \{ 0, 1, 2, p^{\delta} + 1 \}.$$

This observation, together with the fact that $\text{PGL}(2, L)$ is generated by translations, dilations and inversions (for which the corresponding action is reciprocation), motivates us to ascribe $f(\infty) = 0$ if and only if $\deg f < q + 1$ so that $\sim_{2\mathbb{R}}$ preserves the number of roots in $\mathbb{P}^1(\mathbb{L})$. Now we can define

**Definition 3.2.** The $\mathbb{P}^1(\mathbb{L})$-zeroes of a $q$-projective polynomial $f$ is defined as

$$Z_f = \{ x \in \mathbb{P}^1(\mathbb{L}) : f(x) = 0 \},$$

where we define $f(\infty) = 0$ if and only if $\deg f < q + 1$.

Thus we have

**Lemma 3.3.** Let $f \neq 0$ be a $q$-projective polynomial. Then,

(i) $|Z_f|$ is invariant under $\sim_{2\mathbb{R}}$, and

(ii) $|Z_f| \in \{ 0, 1, 2, p^{\delta} + 1 \}$.

**Proof.** Part (ii) is explained before the lemma. We will give a more detailed proof of Part (i) which, actually, also follows from the previous discussion.
Let \( f' \sim_\mathbb{L} f \) via \((\alpha, \mu) \in \mathbb{L}^\times \times \operatorname{PGL}(2, \mathbb{L})\) with \( \mu : x \mapsto \frac{tx + u}{sx + w} \). Suppose \( v \neq 0 \). Define \( T = \mathbb{L} \setminus \{w/v\} \), which satisfies \( \mu(T) = \mathbb{L} \setminus \{t/v\} \). We see by [2] that

\[
x \in T \text{ is a zero of } f' \iff \mu(x) \text{ is a zero of } f.
\]

By [1], we get \( a = 0 \) if and only if

\[
w/v = \mu^{-1}(\infty) \text{ is a zero of } f' \iff \infty \text{ is a zero of } f
\]

if and only if \( \deg f' < q + 1 \). Also by [1], since the coefficient of the \( x^q + 1 \) term of \( f' \) is \( at^q + bt^q + ctv^q + dt^q + 1 = v^q + 1 f(t/v) \), we have

\[
t/v = \mu(\infty) \text{ is a zero of } f \iff \infty \text{ is a zero of } f'
\]

if and only if \( \deg f' < q + 1 \). Combining the three cases we get \( \mu(Z_{f'}) = Z_f \) and \( |Z_f| = |Z_{f'}| \). These facts also trivially follow when \( v = 0 \). \( \square \)

Define the sets (suppressing \( q \) and \( \mathbb{L} \) from the notation for simplicity),

\[
\begin{align*}
D_0 &= \{(0, 0, 0, 0)q\} , \\
D_1 &= [(0, 0, 0, 1)q]\sim_{\mathbb{R}} , \\
D &= D_0 \cup D_1 , \\
\Pi_j &= \{f \in V_{q, \mathbb{L}} \setminus D : |Z_f| = j\} ,
\end{align*}
\]

for \( j \in \{0, 1, 2, p^\delta + 1\} \).

**Lemma 3.4.** We have

(i) \( V_{q, \mathbb{L}} = \bigcup_{j \in \{0, 1, 2, p^\delta + 1\}} \Pi_j \cup D \),

(ii) \( \Pi_1 = [(0, 1, -1, 1)u]\sim_{\mathbb{R}} \) where \( u \in \mathbb{L} \) satisfies \( \alpha_{L/D}(u) = 1 \),

(iii) \( \Pi_{p^\delta + 1} = [(0, 1, -1, 0)q]\sim_{\mathbb{R}} \),

**Proof.** The proof of Part (i) follows from the discussion before the lemma. For Parts (ii) and (iii), we have to show that the action is transitive on the sets \( \Pi_1 \) and \( \Pi_{p^\delta + 1} \). If \( a \neq 0 \), as in the discussion before the lemma, using \( f'(x) = f(x + r) \) first, where \( r \) is an \( L \)-zero of \( f \), and then using the reciprocal \( f''(x) = x^q f'(1/x) \), one shows that \( f \sim_{\mathbb{R}} f'' \) with \( \deg f'' < q + 1 \). Now in both \( p^\delta + 1 \) and one \( \mathbb{P}^1(\mathbb{L}) \)-root cases, \( f'' \) has the form

\[
f''(x) = a + b'x + c'x^q,
\]

with \( -b'/c' = A^{q-1} \) for some \( A \in \mathbb{L}^\times \). One can apply \( x \mapsto x.A \) and then scale to get \( f'' \sim_{\mathbb{R}} x^q - x - d \) for some \( d \in \mathbb{L} \), where \( f \) has \( p^\delta + 1 \) \( \mathbb{P}^1(\mathbb{L}) \)-roots if and only if \( \alpha_{L/D}(d) = 0 \) and \( f \) has one \( \mathbb{P}^1(\mathbb{L}) \)-root if and only if \( \alpha_{L/D}(d) \neq 0 \) by Hilbert’s Theorem 90, and the action is transitive on \( \Pi_{p^\delta + 1} \) since any \( d \) with \( \alpha_{L/D}(d) = 0 \) can be written as \( z^q - z = d \) for some \( z \in \mathbb{L} \) and \( f \sim_{\mathbb{R}} x^q - x \) after the application of \( x \mapsto x + z \).

For the case \( \alpha_{L/D}(d) \neq 0 \), applying \( x \mapsto \epsilon x \) where \( \epsilon \in \mathbb{D}^\times \), and scaling by \( 1/\epsilon \), one can assume \( \alpha_{L/D}(d) = 1 \). Then the transitivity of the action follows again by translations. \( \square \)

When \( \gcd(p^k - 1, p^l - 1) = 1 \), that is to say \( \gcd(k, l) = 1 \) and \( p = 2 \) by Lemma 2.5 we can say more.

**Lemma 3.5.** Let \( p = 2, q = 2^k \), and \( \delta = \gcd(k, l) = 1 \), then we have
(i) \( \Pi_0 = \{ g \sim_{\mathbb{M}} \} \), where \( g \in \Pi_0 \),
(ii) \( \Pi_2 = \{ (0, 0, 1, 0) q \sim_{\mathbb{M}} \} \).
(iii) If \( l \) is odd, then
(a) \( \Pi_1 = \{ (1, 0, 0, 1) q \sim_{\mathbb{M}} \} \).
(iv) If \( l \) is even, then
(a) \( \Pi_0 = \{ (1, 0, 0, u) q \sim_{\mathbb{M}} \} \), where \( u \in L \times (L \times)^{q+1} \).
(b) \( \Pi_3 = \{ (1, 0, 0, 1) q \sim_{\mathbb{M}} \} \).

Proof. (i) This was proved in
- [7, Theorem 2.1] when \( l \) is even, and
- [24, Lemma 7] for general \( l \).
(ii) Since \( \gcd(2^k - 1, 2^l - 1) = 2^{\gcd(k, m)} - 1 = 1 \) by Lemma 2.5, the only option (under translations and dilations) when \( a = 0 \) is \( f \in \{ x, x^q \} \) by the discussion preceding the lemma. Note that \( x^{q+1}(1/x^q) = x \), hence they are reciprocals of each other. If \( a = 1 \), then using a translation and reciprocation, one gets \( f \sim_{\mathbb{M}} f'' \) where \( \deg f'' < q + 1 \). Therefore the action is transitive.
(iii) This is basically Lemma 3.4 (ii) and the fact that \( x^{q+1} + u \) has one root for all \( u \in L \times \) by Lemma 2.5.
(iv) These follow from Lemma 3.4 (iii) and Part (i) of this lemma together with the fact that \( x^{q+1} + u \) has either three or no roots for the given conditions on \( u \in L \times \) by Lemma 2.5.

We can now state the representative set \( S_{q, L} \) we will use.

Lemma 3.6. Let \( p = 2, q = 2^k, \delta = \gcd(k, l) = 1 \), and
\[
S = \{(0, 0, 0, 0)_q, (0, 0, 0, 1)_q, (0, 0, 1, 0)_q \} \cup \{(1, 0, 0, a)_q : a \in L \times \}.
\]
(i) If \( l \) is odd then
\[
S_{q, L} = S \cup \{(0, 1, 1, 0)_q \} \cup \Pi_0.
\]
(ii) If \( l \) is even then
\[
S_{q, L} = S \cup \Pi_1.
\]

Then \( S_{q, L} \) is a representative set for \( V_{q, L} \).

4. Further lemmas

In this section we will give the results that are needed in the classification.

4.1. The zeroes of \( x^{q+1} + x + b \). Now we are going to restrict ourselves to a specific type of \( q \)-projective polynomials, namely
\[
P_b(x) = x^{q+1} + x + b,
\]
for \( b \in L \). Bluher studied these polynomials [6] and determined the cardinalities of the sets
\[
I_j = \{ b \in L : P_b \in \Pi_j \},
\]
where \( j \in \{0, 1, 2, p^j + 1\} \). In this section we are interested only in the \( p = 2 \) case and \( \gcd(k, l) = 1 \) where \( \mathbb{L} = \mathbb{F}_2^l \) and \( q = 2^k \). In the definitions of \( I_j \) and \( P_b \) (along with previously defined sets) we suppress \( q \) and \( \mathbb{L} \) for notational simplicity.

The following is an important result on combinatorics of finite fields proved by Dillon and Dobbertin \[19\].

**Lemma 4.1.** Let \( q = 2^k \) and \( \gcd(k, l) = 1 \). The set \( I_1 \) is a

\[
\begin{align*}
&\text{(i) } (2^l - 1, 2^{l-1} - 1, 2^{l-2} - 1)\text{-difference set in } \mathbb{L}^\times \text{ if } l \text{ is odd, and} \\
&\text{(ii) } (2^l - 1, 2^{l-1}, 2^{l-2})\text{-difference set in } \mathbb{L}^\times \text{ if } l \text{ is even.}
\end{align*}
\]

**Proof.** Let \( d = 4^k - 2^k + 1 \) and

\[
\Delta = \begin{cases} \{x^d + (x + 1)^d + 1 : x \in \mathbb{L} \setminus \mathbb{F}_2\} & \text{if } l \text{ is odd, and} \\
\mathbb{L}^\times \setminus \{x^d + (x + 1)^d + 1 : x \in \mathbb{L} \setminus \mathbb{F}_2\} & \text{if } l \text{ is even.}
\end{cases}
\]

Dillon and Dobbertin showed \[19\] Theorem A\) that \( \Delta \) is a difference set with indicated (Singer) parameters.

The fact that \( I_1 = 1/\Delta \) was shown in \[29\] Theorem 1\) (see also \[23\] Theorem 5.13\]). \( \square \)

In the next lemma we show that, since \( \gcd(2^k - 1, 2^l - 1) = 2^{\gcd(k,l)} - 1 = 1 \), we can easily determine the sets \( I_1, I_2 \) and \( I_3 \). The map \( \rho \) appears quite frequently when one works with projective polynomials, for instance, in Serre’s proof that \( \text{PSL}(2, q) \) is the Galois group of the equation \( x^{q+1} - xy + 1 = 0 \) for arbitrary prime power \( q \) (see \[1\] pp. 131–132). We provide a simple proof for \( \gcd(k, l) = 1 \) again in characteristic 2.

**Lemma 4.2.** Let \( q = 2^k, \gcd(k, l) = 1 \) and

\[
\rho : \mathbb{L} \setminus \mathbb{F}_2 \to \mathbb{L} \setminus \mathbb{F}_2, \\
x \mapsto x^{q^2+1} = \frac{(x^q + x)^{q+1}}{\rho}.
\]

We have

\[
\begin{align*}
&\text{(i) } \{\rho(x) : x \in \mathbb{H} \setminus \mathbb{F}_2\} = I_1, \\
&\text{(ii) } \{\rho(x) : x \in \mathbb{H} \setminus \mathbb{F}_2\} = I_3, \\
&\text{(iii) } I_2 = \{0\}, \\
&\text{(iv) } \{x^{q+1} + x : x \in \mathbb{L}\} = I_1 \cup I_2^{[2]} \cup I_3^{[3]}.
\end{align*}
\]

**Proof.** Let \( b \in I_1 \cup I_2 \cup I_3 \) and \( f = P_b = x^{q+1} + x + b \). Let \( r \in \mathbb{L} \) be a root of \( f \). Then

\[
f(x + r) = (x + r)^{q+1} + x + r + b \\
= x^{q+1} + r x^q + (r + 1)^q x + r^{q+1} + r + b \\
= x^{q+1} + r x^q + (r + 1)^q x \\
\sim_{\mathbb{F}_2} (r + 1)^{q} x^q + r x + 1 = f''(x)
\]

Then \( |Z_f| = 2 \) if and only if \( |Z_{f''}| = 1 \) if and only if \( r \in \mathbb{F}_2 \). Thus \( b = 0 \) and Part (iii) follows. Otherwise we have \( A \in \mathbb{L}^\times \) such that

\[
A^{q-1} = \frac{r}{(r + 1)^q}.
\]
since \( x \mapsto x^{q-1} \) is bijective on \( L \) by Lemma 2.5. We have \( f \in \Pi_1 \) if and only if \( \text{tr} \left( \frac{1}{A} r \right) = 1 \) and \( f \in \Pi_3 \) if and only if \( \text{tr} \left( \frac{1}{A} r \right) = 0 \) by Hilbert’s Theorem 90. Now, let \( h \in \mathbb{L}^\times \) satisfy

\[
\frac{1}{A} = h^q,
\]

That is to say

\[
1_A = h^q r \iff \frac{1}{A^{q-1}} = h^{q(q-1)} r^{q-1} = \frac{(r+1)^q}{r}.
\]

Thus, recalling \( r \notin \mathbb{F}_2 \),

\[
h^{q-1} = \frac{r+1}{r} = 1 + \frac{1}{r}.
\]

Therefore for each \( r \in \mathbb{L} \setminus \mathbb{F}_2 \), there is unique \( h \in \mathbb{L} \setminus \mathbb{F}_2 \), where \( h \in \mathcal{H} \setminus \mathbb{F}_2 \) if and only if \( f \in \Pi_3 \) and \( h \in \mathcal{H} \setminus \mathbb{F}_2 \) if and only if \( f \in \Pi_1 \). Or, equivalently

\[
r = \frac{h}{h + h^q}.
\]

The following lemma is key to our classification. It will prove that the Kim function \( \kappa \) exists as a theorem of small cases, using the properties of Dillon-Dobbertin difference sets with Singer parameters.

**Lemma 4.3.** Let \( l > 3 \), \( q = 2^k \) and \( \gcd(k, l) = 1 \). For all

- \( d \in \mathbb{L}^\times \) if \( l \) is odd, and
- \( d \in \mathbb{L}^\times \setminus (\mathbb{L}^\times)^{q+1} \) if \( l \) is even, we have

\[
d I_3 \cap (I_1 \cup I_2 \cup I_3) \neq \emptyset.
\]

**Proof.** By Lemma 4.2 (iii), \( I_2 = \{0\} \) and therefore \( d I_3 \cap I_2 = \emptyset \). Also the \( d = 1 \) case is clear. Let

\[
M = \frac{I_1 \cup I_3^{[3]}}{I_3^{[3]}}.
\]

The claim of the lemma is equivalent to the claim that for all \( d \in \mathbb{L} \setminus \mathbb{F}_2 \),

\[
\text{mult}_M(d) > 0.
\]

We have

\[
M = \frac{I_1}{I_3^{[3]}} \cup \frac{I_3^{[3]}}{I_3^{[3]}},
\]

and

\[
J = \frac{I_1 \cup I_3^{[3]}}{I_1 \cup I_3^{[3]}} = \frac{M \cup I_1}{I_1} \cup \frac{I_3^{[3]}}{I_1}.
\]

It is clear by Lemma 4.2 (iii) and (iv) that

\[
I_1 \cup I_3^{[3]} = \{ x^{q+1} + x : x \in \mathbb{L} \setminus \mathbb{F}_2 \}.
\]

For \( x, y, d \in \mathbb{L} \setminus \mathbb{F}_2 \), we will find the number of solutions of

\[
\frac{x^{q+1} + x}{y^{q+1} + y} = d,
\]
which is (for \( y, d \in \mathbb{L} \setminus \mathbb{F}_2 \) and \( x \in \mathbb{L}^x \setminus \{1/y\} \)) the same as the number of solutions of
\[
\frac{(xy)^{q+1} + xy}{y^{q+1} + y} = \frac{x^{q+1}y^q + x}{y^q + 1} = d.
\]
Or, equivalently
\[
y^q(x^{q+1} + d) = (x + d).
\]
For all \( x \in \mathbb{L} \setminus \mathbb{F}_2 \) such that \( x^{q+1} \neq d \) or \( x \neq d \), there exists a (unique) \( y \in \mathbb{L} \setminus \mathbb{F}_2 \). The equality holds when \( x = 1/y \) if and only if \( y^q d = d \), that is to say \( x = y = 1 \).

Thus
\[
\text{mult}_J(d) = \begin{cases} 
2^l - 4 & \text{if } l \text{ is odd}, \\
2^l - 6 & \text{if } l \text{ is even and } d \in (\mathbb{L}^x)^{q+1}, \\
2^l - 3 & \text{if } l \text{ is even and } d \in \mathbb{L}^x \setminus (\mathbb{L}^x)^{q+1},
\end{cases}
\]
since \( \gcd(2^k + 1, 2^l - 1) = 3 \) if \( l \) is even and 1 if \( l \) is odd. Since \( I_1 \) is a difference set with Singer parameters, we have by Lemma 4.1
\[
\text{mult}_{I_1/I_1}(d) = \begin{cases} 
2^{l-2} - 1 & \text{if } l \text{ is odd}, \\
2^{l-2} & \text{if } l \text{ is even}.
\end{cases}
\]
Since for all \( i \in I_3 \) we have at most one \( i \in I_1 \) since \( I_1 \) is a set by Lemma 4.2 (i), we have the trivial bound \( \text{mult}_{I_3^{[3]}/I_1}(d) \leq |I_3^{[3]}| \). By Lemma 4.2 (ii), we have,
\[
\text{mult}_{I_3^{[3]}/I_1}(d) \leq \begin{cases} 
2^{l-1} - 1 & \text{if } l \text{ is odd}, \\
2^{l-1} - 2 & \text{if } l \text{ is even}.
\end{cases}
\]
Note that by the definition of \( J \), we must have,
\[
\text{mult}_J(d) = \text{mult}_M(d) + \text{mult}_{I_1/I_1}(d) + \text{mult}_{I_3^{[3]}/I_1}(d).
\]
Now assume \( \text{mult}_M(d) = 0 \). If \( l \) is odd, this means
\[
2^l - 4 \leq 0 + 2^{l-2} - 1 + 2^{l-1} - 1,
\]
\[
2^{l-2} \leq 2,
\]
which means \( l \leq 3 \). Similarly for \( l \) is even and \( d \in \mathbb{L}^x \setminus (\mathbb{L}^x)^{q+1} \),
\[
2^l - 3 \leq 0 + 2^{l-2} + 2^{l-1} - 2,
\]
\[
2^{l-2} \leq 1,
\]
which means \( l \leq 2 \).

The claim also holds for \( d \in (\mathbb{L}^x)^{q+1} \) similarly but skipped since it will not be used and requires computerized check for \( l = 4 \). \(\square\)

4.2. Results on fractional projective permutations of \( \mathbb{F}_q^1(\mathbb{L}) \). Given two \( q \)-projective polynomials \( f(x, 1), g(x, 1) \) over \( \mathbb{L} \), we can define a fractional projective map \( x \mapsto f(x, 1)/g(x, 1) \) on \( \mathbb{F}_q^1(\mathbb{L}) \) whenever \( f \) and \( g \) do not have a common zero. Fractional projective permutations over a finite field \( \mathbb{L} \) of order \( p^l \) has been classified for every parameter \( p, k, l \) [23]. Recall the specific Dembowski-Ostrom polynomials of type \([1] \). The monomial Gold maps \( X \mapsto X^s \) where \( s \in \{q + 1, (q + 1)r, qr + 1, q + r\} \) on \( \mathbb{F}_{p^r} \) with \( q = p^k \) and \( r = p^l \) have been shown to be connected to the fractional projective permutations.
Identifying $\mathbb{F}_{p^k} = L(ξ) = Lξ + L \cong L \times L$, the above Gold maps can be written as \((q,q)\)-biprojective polynomials $G_s(x, y) = (f_s(x, y), g_s(x, y))$ using $X = xξ + y$.

The following lemma has been proved for general parameters in [23]. Here we include only the results necessary for our treatment.

**Lemma 4.4.** Let $p = 2$, $q = p^k$, $r = p^l$ and $\gcd(k, l) = 1$.

- If $l$ is odd, then
  $$
x \mapsto x^{q+1} + c \xrightarrow{\mathbb{P}^l(L)} \text{permutes } \mathbb{P}^l(L) \text{ if and only if } c \in \mathbb{F}_2 \text{ and } d = 1.
  $$

- If $l$ is even and $f(x, 1) = 0 = g(x, 1)$ does not hold for $x \in \mathbb{P}^l(L)$, then the fractional projective map
  $$
x \mapsto f(x, 1)/g(x, 1)
  $$
  permutes $\mathbb{P}^l(L)$ if and only if $(f, g) \approx L G_{q+1} \text{ or } (f, g) \approx L G_{q+r}$.

Note that in the even case $G_{q+1}$ and $G_{q+r}$ are APN, since $\gcd(k, l) = \gcd(k, 2l) = \gcd(k + l, 2l) = 1$ by [20] which states that $G_{2i+1}$ is APN over $\mathbb{F}_{2^n}$ if and only if $\gcd(i, n) = 1$.

### 5. The classification

First we will prove a necessary gcd-condition on a \((q,q)\)-biprojective APN function $F$.

**Proposition 5.1.** Let $q = 2^k$ and $\gcd(k, l) > 1$. Then $F \in \mathcal{F}_{q,L}$ is not APN.

**Proof.** Let $F = (f, g) = ((a_0, b_0, c_0, d_0)_q, (a_1, b_1, c_1, d_1)_q)$. By Lemma 2.3 if $F$ is APN, then

$$
b_1x^q + c_1x = d_1(y^q + y),
$$

$$
b_0x^q + c_0x = d_0(y^q + y),
$$

has two solutions in $L \times L$. Solutions to this equation pair include $(x, y) \in \{0\} \times \text{Ker}(y^q + y)$. Thus $\gcd(k, l) = 1$. $\square$

Now we can concentrate on the case $\gcd(k, l) = 1$. We can assume $(f, g) \in \mathcal{S}_{q,L} \times \mathcal{V}_{q,L}$, where $\mathcal{S}_{q,L}$ is found in Lemma 3.6. We will first deal with the case $f \in S$ (see Lemma 3.6 for the definitions of $S$ and $\mathcal{S}_{q,L}$ we use).

#### 5.1. The case $f \in S$

**Proposition 5.2.** Let $q = 2^k$, $l > 3$, $\gcd(k, l) = 1$ and

$$
F : L \times L \to L \times L,
$$

$$
(x, y) \mapsto (f(x, y), g(x, y)),
$$

where $f \in S \subset \mathcal{S}_{q,L}$ and $g \in \mathcal{V}_{q,L}$. Then $F$ is not APN.

**Proof.** We will analyze each function $f \in S$ case by case. We let $g = (a_1, b_1, c_1, d_1)_q$. 

\[ f \in \{(0,0,0,0)_q, (0,0,0,1)_q\}. \]

We have \( D_f^\infty(x,y) = 0 \) for all \((x,y)\) and \( D_g^\infty(x,y) = 0 \) if and only if
\[ a_1 x^q + a_1 x = c_1 y^q + b_1 y. \]

If \( a_1 = 0 \) or \( b_1 = c_1 = 0 \), then the claim easily follows since \((x,y) \in \mathbb{L} \times \{0\} \) (or \( \{0\} \times \mathbb{L}, \) resp.) satisfy the equality. Otherwise \(|\text{Im}(a_1 x^q + a_1 x) \cap \text{Im}(c_1 y^q + b_1 y)| \geq 2^{l-2}\), since both image sets are at least \( l - 1 \) dimensional \( \mathbb{F}_2 \)-vector spaces which have to intersect at a vector space with dimension at least \( l - 2 \).

\[ f = (0,0,1,0)_q. \]

Since \((f,g) \approx_2 (f,rf + sg)\) if and only if \( s \neq 0 \) we can assume that \( c_1 = 0 \). The equalities for \( D_f^u(x,y) = 0 = D_g^u(x,y) = 0 \) for \( u \in \{0,\infty\} \) give
\[
D_f^0(x,y) = x = 0,
\]
\[
D_g^0(x,y) = b_1 x^q + d_1 y^q + d_1 y = 0,
\]
and implying that \( a_1 \neq 0 \) and \( d_1 \neq 0 \). Thus, setting \( a_1 = 1 \) by the scaling action, we will check the common solutions of
\[
D_f^u(x,y) = x + uy^q = 0,
\]
\[
D_g^u(x,y) = (u + b_1)x^q + u^q x + d_1 y^q + (b_1 u^q + d_1)y = 0,
\]
for \( u \in \mathbb{L}^\times \). Replacing \( x \) by \( uy^q \) in the second equation
\[
D_g^u(x,y) = (u + b_1)(uy^q)^q + u^q(uy^q) + d_1 y^q + (b_1 u^q + d_1)y = 0,
\]
\[
= (u^{q+1} + b_1 u^q)y^{q^2} + d_1 y^q + (b_1 u^q + d_1)y = 0,
\]
\[
= u^{q+1}(y^{q^2} + y) + b_1 u^q(y^{q^2} + y) + d_1(y^q + y) = 0.
\]
Thus for every \( u \in \mathbb{L}^\times \), all \((uy^q,y)\) for \( y \in \mathbb{F}_2 \) give a solution. To be APN, these should be the only solutions. We will use the fact that \( y^q + y = h \in \mathcal{H} \setminus \{0\} \), for \( y \in \mathbb{L} \setminus \mathbb{F}_2 \) by Hilbert’s Theorem 90. If \( b_1 = 0 \), then
\[
\frac{d_1}{u^{q+1}} = \frac{h^q}{h}
\]
has a solution for every \( h \in \mathcal{H} \setminus \{0\} \). Now, applying \( u \mapsto ub_1 \) we get, by setting \( d^q = d_1 / b_1^{q+1} \),
\[
u^{q+1} h^q + u^q(h^q + h) + d^q h = 0,
\]
\[
v^{q+1} + v(h^q + h) + dh^q = 0,
\]
setting \( v = d/u \) and then multiplying the equality by \( v^{q+1}/d^q \). Now if \( 1 \in \mathcal{H} \) (i.e., \( l \) is even) then \( d \not\in (\mathbb{L}^\times)^{q+1} \) for \( F \) to be APN. For \( h \in \mathcal{H} \setminus \mathbb{F}_2 \), setting \( v = x((h^q + h)/h)^q \), we get
\[
x^{q+1} + x + \frac{dh^{q+7}}{(h^q + h)^{q+1}} = 0.
\]
We have
\[
\begin{align*}
\{(h^{q+7}/(h^q + h)^{q+1} : h \in \mathcal{H} \setminus \mathbb{F}_2\} &= \{h^{q+1}/(h^q + h)^{q+1} : h \in \mathcal{H} \setminus \mathbb{F}_2\} = I_3^{[3]},
\end{align*}
\]
by Lemma 4.2 (ii), since \( h \in \mathcal{H} \) if and only if \( h^q \in \mathcal{H} \). Now \( F \) is APN if and only if 
\( dI_3 \cap (I_1 \cup I_2 \cup I_3) = \emptyset \). By Lemma 4.3 we have 
\( dI_3 \cap (I_1 \cup I_2 \cup I_3) \neq \emptyset \), for \( l > 3 \) and we are done.

- \( f = (1, 0, 0, d_0)_q \) for \( d_0 \in \mathbb{L}^* \).
  
  We can assume \( a_1 = 0 \). We have
  \[
  D_f^0(x, y) = d_0(y^q + y) = 0, \\
  D_g^0(x, y) = b_1x^q + c_1x + d_1(y^q + y) = 0.
  \]
  Thus either \( c_1 = 0 \) or \( b_1 = 0 \) (but not both), and since \( (0, b_1, 0, d_1)_q \sim_{\mathbb{F}_q} (0, 0, c_1, d_1)_q \sim_{\mathbb{F}_q} (0, 0, 1, 0)_q \)
  we are done as we have already handled that case before.

\[\square\]

**Remark 5.3.** In the proof of the case \( f = (0, 0, 1, 0)_q \) we assumed \( l > 3 \) and we used Lemma 4.3 to show that \( F \) is not APN. For \( l = 3 \), the necessary and sufficient condition

\[dI_3 \cap (I_1 \cup I_2 \cup I_3) = \emptyset,\]

holds for \( d \in J = \{\omega, \omega^2, \omega^4\} \) where \( \omega \in \mathbb{F}_{2^3} \) satisfying \( \omega^3 + \omega + 1 = 0 \). In this case

\[
I_0 = \{\omega, \omega^2, \omega^4\}, \\
I_1 = \{\omega^3, \omega^5, \omega^6\}, \\
I_2 = \{0\}, \text{ and} \\
I_3 = \{1\}.
\]

It is easy to see the direct product satisfies \( JI_3 = I_0 \). Thus \( F : \mathbb{F}_{2^3} \times \mathbb{F}_{2^3} \to \mathbb{F}_{2^3} \times \mathbb{F}_{2^3} \), with 
\( F = ((0, 0, 1, 0)_2, (1, b_1, 0, d_1)_2) \) for \( b_1, d_1 \in \mathbb{F}_{2^3} \) is APN if and only if \( \omega^{2^l} = d_1/b_1^3 \). These are precisely the Kim \( \kappa \) functions (up to \( \sim_{\mathbb{F}_q} \) equivalence).

**Remark 5.4.** Note that the case \( (f, g) \in \{(1, 0, 0, 1)_q\} \times \Pi_1 \) proved as a subcase in Proposition 5.2

generalizes the results in [12] [11] that show that the class of functions satisfying the (generalized) butterfly structure are not APN when \( l > 3 \) is odd. These functions are by definition [12],

\[B_{q, L} = \{(x + ay)^{q+1} + (by)^{q+1}, (y + ax)^{q+1} + (bx)^{q+1} : a, b \in \mathbb{L}^*\}.\]

It is easy to see via \( x \mapsto x + ay \) and then \( y \mapsto y/b \) for the left component (and similarly \( y \mapsto y + ax \) and \( x \mapsto x/b \) for the right component) that \( (f, g) \in B_{q, L} \subset \Pi_1 \times \Pi_1 \).

Note that \( \Pi_1 \times \Pi_1 \) contains functions (CCZ-equivalent to permutations) that are not contained directly in \( B_{q, L} \) and whether the CCZ-equivalence class (or \( \approx_L \) class) of \( B_{q, L} \) covers all such functions is not covered in [12] [11] and seems to be difficult to solve. The question is easy to answer for the right action of \( GL(2, \mathbb{L}) \) together with scaling on both components (the natural subgroup action
\( (\mathbb{L}^* \times \mathbb{L}^*) \times GL(2, \mathbb{L}) \) that preserves inclusion in \( \Pi_1 \)). After the transformations \( (x \mapsto x + ay \) and then \( y \mapsto y/b) \) on the left part and applying all \( GL(2, \mathbb{L}) \) transformations stabilizing the left part \( (1, 0, 0, 1)_q \)
(generated by \( (x, y) \mapsto (y, x) \)) and scaling on the right side, we see

\[B_{q, L}' = \{(1, 0, 0, 1)_q \times \left(\{h_{a,b,c}(x, y) : a, b, c \in \mathbb{L}^*\} \cup \{h_{a,b,c}(y, x) : a, b, c \in \mathbb{L}^*\}\right), \]

where

\[h_{a,b,c}(x, y) = c((a + 1)y/b + ax)^{q+1} + (bx + ay)^{q+1}.\]
The cardinality of this set is $|B_{q,\Pi}| \leq 2^{3l+1}$ whereas $|\Pi_1| = (2^{2l} - 1)(2^{2l} - 2^l)/2 \approx 2^{4l-1}$. Thus $B_{q,\Pi}$ is strictly included in $\{(1,0,0,1)_q\} \times \Pi_1$.

Note also that the butterfly structure is defined only for odd $l$ whereas Proposition 5.2 covers the even case as well. We also note that $\Pi_1 \times \Pi_1$ and, in particular, the functions from the generalized butterfly construction seems to be a good source for cryptographically interesting functions. The engineering aspects of the butterflies were explained in [11].

5.2. The even $l$ case. By Lemma 3.6 we can assume $f \in \Pi_1$ when $l$ is even.

**Proposition 5.5.** Let $q = 2^k$, $l > 3$ even, $r = 2^l$, $\gcd(k,l) = 1$ and

$$F : \mathbb{L} \times \mathbb{L} \rightarrow \mathbb{L} \times \mathbb{L},$$

$$(x, y) \mapsto (f(x, y), g(x, y)),$$

where $f \in \Pi_1$ and $g \in \mathcal{V}_{q,\Pi}$. Then $F$ is APN if and only if $F \approx_2 G_{q+1}$ or $F \approx_2 G_{q+r}$.

**Proof.** By Lemma 3.6 and Proposition 5.2 we must have $g \in \Pi_1$. Assume $f(x_0, 0) = 0 = g(x_0, 1)$ for some $x_0 \in \mathbb{P}^1(\mathbb{L})$, then since both $f, g$ have only one $\mathbb{P}^1(\mathbb{L})$-zero, there exists $x_1 \in \mathbb{L}$ such that $f(x_1, 1)g(x_1, 1) \neq 0$. Now $f(x, 1) + rg(x, 1) = 0$ has at least two $\mathbb{P}^1(\mathbb{L})$-zeroes $\{x_0, x_1\}$ where the nonzero $r$ is chosen to satisfy $r = \frac{f(x_1, 1)}{g(x_1, 1)}$. Thus $(f, f + rg) \approx_2 (f, g)$ is not APN by Proposition 5.2.

Therefore we can assume that $f$ and $g$ do not have a common zero. We must have $rf(x, 1) + sg(x, 1) \in \Pi_1$ for every $(r, s) \in \mathbb{L} \times \mathbb{L} \setminus \{(0, 0)\}$. That is to say

$$\pi(x) = \frac{f(x, 1)}{g(x, 1)} = \frac{s}{r}$$

has a unique solution $x \in \mathbb{P}^1(\mathbb{L})$ for every $s/r \in \mathbb{P}^1(\mathbb{L})$, i.e., $x \mapsto \pi(x)$ is bijective. That is to say

$$F \approx_2 G_{q+1} \text{ or } F \approx_2 G_{q+r},$$

by Lemma 4.4.

5.3. The odd $l$ case. By Lemma 3.6 we can assume that $f \in \{(0,1,1,0)_q\} \cup \Pi_0$ when $l$ is odd.

**Proposition 5.6.** Let $q = 2^k$, $l > 3$ odd, $r = 2^l$, $\gcd(k,l) = 1$ and

$$F : \mathbb{L} \times \mathbb{L} \rightarrow \mathbb{L} \times \mathbb{L},$$

$$(x, y) \mapsto (f(x, y), g(x, y)),$$

where $f \in \{(0,1,1,0)_q\} \cup \Pi_0$ and $g \in \mathcal{V}_{q,\Pi}$. Then $F$ is APN if and only if

- $F \approx_2 G_{q+1}$ if $k$ is odd, and
- $F \approx_2 G_{q+r}$ if $k$ is even.

**Proof.** It is clear by Proposition 5.2 that $f, g \in \Pi_3 \cup \Pi_0$. Now, if $f, g \in \Pi_0$ then $rf + sg \in \Pi_0$ for all $(r, s) \in \mathbb{L} \times \mathbb{L} \setminus \{(0, 0)\}$ is absurd. Thus, whenever $rf + sg$ has a $\mathbb{P}^1(\mathbb{L})$-solution it must have exactly three $\mathbb{P}^1(\mathbb{L})$ solutions again by Proposition 5.2. Since, $(f, g) \approx_2 (rf + sg, g)$, we can assume that $f = (0,1,1,0)_q$ and $g \in \Pi_0 \cup \Pi_3$. Let $g = (a, b, c, d)_q$. We can assume by the left action of
GL(2, \mathbb{L}), b = 0, and by scaling, \( a = 1 \) (note that \( a = 0 \) is impossible since it implies \( g \in \Pi_2 \)). Thus \( g = (1, 0, c, d)_q \). We have
\[
D_f^\infty(x, y) = y^q + y = 0,
\]
\[
D_g^\infty(x, y) = (x^q + x) + cy^q = 0,
\]
which always have \((x, y) \in \mathbb{F}_2 \times \{0\}\) as solutions. Thus, \( \text{tr} (c) = 1 \), so that \( \mathbb{F}_2 \times \{1\} \) do not give more solutions, in particular \( c \neq 0 \). Also
\[
D_f^0(x, y) = x^q + x = 0,
\]
\[
D_g^0(x, y) = cx + d(y^q + y) = 0,
\]
implying \( d \neq 0 \).

Now we will introduce the main argument: If \( F = (f, g) \) is APN then \( rf + g \in \Pi_0 \cup \Pi_3 \). Let us determine the conditions on \( F \) when \( rf + g \in \Pi_1 \). We will show that this is always the case unless \( F \) is equivalent to a Gold map.

By Lemma 3.5 (iii), \([(1, 0, 0, 1)_q]_{\sim M} = \Pi_1 \). Let
\[
A_{\alpha, \beta, u, v} = \begin{pmatrix} \alpha & u\alpha \\ \beta & v\beta \end{pmatrix}
\]
where \( \alpha, \beta \in \mathbb{L} \setminus \mathbb{F}_2 \) and \( u, v \in \mathbb{L} \) with \( u \neq v \) so that \( \det(A_{\alpha, \beta, u, v}) = \alpha \beta (u + v) \neq 0 \).

Let \( h = (1, 0, 0, 1)_q \) and consider the right action of PGL(2, \mathbb{L}) (viewing \( h \) as a univariate \( q \)-projective polynomial),
\[
h'(x) = \beta^{q+1} (x + v)^{q+1} h(\mu_{\alpha, \beta, u, v}(x)),
\]
where
\[
\mu_{\alpha, \beta, u, v}(x) : x \mapsto \frac{\alpha(x + u)}{\beta(x + v)}.
\]
Equating the terms of \( h' \) and \( rf + g \), we get
\[
\alpha^{q+1} + \beta^{q+1} = 1,
\]
\[
\alpha^{q+1} u + \beta^{q+1} v = r,
\]
\[
\alpha^{q+1} u^q + \beta^{q+1} v^q = r + c,
\]
\[
\alpha^{q+1} u^q + \beta^{q+1} v^q = d.
\]
Since \( x \mapsto x^{q+1} \) is bijective and \( r \in \mathbb{L} \), we can rewrite these as
\[
\gamma (u^q + u) + (\gamma + 1) (v^q + v) = c,
\]
\[
\gamma u^{q+1} + (\gamma + 1) v^{q+1} = d,
\]
where \( \gamma = \alpha^{q+1} = 1 + \beta^{q+1} \). Since \( \alpha, \beta \in \mathbb{L} \setminus \mathbb{F}_2 \), so is \( \gamma \) and for all \( \gamma \in \mathbb{L} \setminus \mathbb{F}_2 \), we can find \( \alpha \) and \( \beta \) satisfying the above equalities. Equivalently,
\[
(5) \quad \gamma (u^q + u + c) = (\gamma + 1) (v^q + v + c),
\]
\[
(6) \quad \gamma (u^{q+1} + d) = (\gamma + 1) (v^{q+1} + d).
\]
Note that \( \text{tr} (c) = 1 \) and \( \gamma \notin \mathbb{F}_2 \), therefore neither side of \( (5) \) vanishes. Thus we can divide \( (6) \) by \( (5) \) side by side to get
\[
(7) \quad \varphi_{c, d}(u) = \varphi_{c, d}(v),
\]
where
\[ \varphi_{c,d}(x) : x \mapsto x^{q+1} + d. \]
Clearly (5) and (6) hold together if and only if (5) and (7) hold together.

Now assume \( \varphi_{c,d} \) is not bijective on \( L \). Then there exist \( u, v \in L \) such that \( \varphi_{c,d}(u) = \varphi_{c,d}(v) \) with \( u + v \not\in F_2 \). It is clear that
\[
\varphi_{c,d}(x) + \varphi_{c,d}(x + 1) = x^{q+1} + x^{q+1} + d \neq 0,
\]
since \( \text{tr}(1) = 1 \). For such \( u, v \), (5) becomes
\[
uq + u + c = \frac{\gamma + 1}{\gamma} = 1 + \frac{1}{\gamma} \not\in F_2.
\]
Thus, selecting \( \alpha, \beta \in L \setminus F_2 \) we can produce such \( \gamma \). Hence, \( \varphi_{c,d} \) must be bijective, and by Lemma 4.4, we must have \( c = d = 1 \) and \( g = (1, 0, 1, 1)_q \).

Now let \( \langle \xi \rangle = F_4^X \). Any \( X \in F_{2l} \) can be written as \( X = x + y\xi \) where \( x, y \in L \). We have
\[
\xi^{2^k} = \begin{cases} 
\xi + 1 & \text{if } k \text{ is odd}, \\
\xi & \text{if } k \text{ is even}.
\end{cases}
\]
Now if \( k \) is odd, then
\[
(x + y\xi)^{q+1} = x^{q+1} + xy^q + y^{q+1} + \xi(x^qy + xy^q)
\]
\[\cong (x^{q+1} + xy^q + y^{q+1}), x^qy + xy^q)\]
\[\cong \xi ((0, 1, 1, 0)_q, (1, 0, 1, 1)_q),\]
and if \( k \) is even,
\[
(x + y\xi)^{q+r} = x^{q+1} + x^qy + y^{q+1} + \xi(x^qy + xy^q)
\]
\[\cong (x^{q+1} + x^qy + y^{q+1}), x^qy + xy^q)\]
\[\cong \xi ((x^{q+1} + xy^q + y^{q+1}), x^qy + xy^q)\]
\[\cong \xi ((0, 1, 1, 0)_q, (1, 0, 1, 1)_q),\]
using \( (x, y) \mapsto (y, x) \) in the penultimate line, proving our assertion that \( (f, g) \approx L G_{q+1} \) when \( k \) is odd, and \( (f, g) \approx L G_{q+r} \) when \( k \) is even. Note that when \( l \) is odd and \( \gcd(k, l) = 1 \), we have \( \gcd(k, 2l) = 1 \) if \( k \) is odd and \( \gcd(l - k, 2l) = 1 \) if \( k \) is even. By [20], these maps are APN since \( q + r = q(1 + r/q) = 2^k(1 + 2^{l-k}) \).

5.4. Proof of Theorem 1.1. Now, Propositions 5.1, 5.2, 5.5 and 5.6 together with Lemma 3.6 proves Theorem 1.1.

6. Acknowledgments

The author would like to thank Claude Carlet for his comments. He also thanks Lukas Kölsch for many discussions that improved the treatment considerably.
