1 Introduction

It is well-known that Hamilton-Jacobi theory is an important research subject in mathematics and analytical mechanics, see Abraham and Marsden [1], Arnold [2] and Marsden and Ratiu [19], and
the Hamilton-Jacobi equation is also fundamental in the study of the quantum-classical relationship in quantization, and it also plays an important role in the study of stochastic dynamical systems, see Woodhouse [33], Ge and Marsden [10], and Lázaro-Camí and Ortega [12]. For these reasons it is described as a useful tool in the study of Hamiltonian system theory, and has been extensively developed in past many years and become one of the most active subjects in the study of modern applied mathematics and analytical mechanics.

Just as we have known that Hamilton-Jacobi theory from the variational point of view is originally developed by Jacobi in 1866, which state that the integral of Lagrangian of a mechanical system along the solution of its Euler-Lagrange equation satisfies the Hamilton-Jacobi equation. The classical description of this problem from the generating function and the geometrical point of view is given by Abraham and Marsden in [1] as follows: Let \( Q \) be a smooth manifold and \( TQ \) the tangent bundle, \( T^*Q \) the cotangent bundle with a canonical symplectic form \( \omega \) and the projection \( \pi_Q : T^*Q \to Q \) induces the map \( T\pi_Q : TT^*Q \to TQ \).

**Theorem 1.1** Assume that the triple \((T^*Q, \omega, H)\) is a Hamiltonian system with Hamiltonian vector field \( X_H \), and \( W : Q \to \mathbb{R} \) is a given generating function. Then the following two assertions are equivalent:

(i) For every curve \( \sigma : \mathbb{R} \to Q \) satisfying \( \dot{\sigma}(t) = T\pi_Q(X_H(dW(\sigma(t)))) \), \( \forall t \in \mathbb{R} \), then \( dW \cdot \sigma \) is an integral curve of the Hamiltonian vector field \( X_H \).

(ii) \( W \) satisfies the Hamilton-Jacobi equation \( H(q^i, \frac{\partial W}{\partial q^i}) = E \), where \( E \) is a constant.

From the proof of the above theorem given in Abraham and Marsden [1], we know that the assertion (i) with equivalent to Hamilton-Jacobi equation (ii) by the generating function, gives a geometric constraint condition of the canonical symplectic form on the cotangent bundle \( T^*Q \) for Hamiltonian vector field of the system. Thus, the Hamilton-Jacobi equation reveals the deeply internal relationships of the generating function, the canonical symplectic form and the dynamical vector field of a Hamiltonian system.

Now, it is a natural problem how to generalize Theorem 1.1 to fit the nonholonomic systems and their reduced systems. Note that if take that \( \gamma = dW \) in the above Theorem 1.1, then \( \gamma \) is a closed one-form on \( Q \), and the equation \( d(H \cdot dW) = 0 \) is equivalent to the Hamilton-Jacobi equation \( H(q^i, \frac{\partial W}{\partial q^i}) = E \), where \( E \) is a constant, which is called the classical Hamilton-Jacobi equation. This result is used the formulation of a geometric version of Hamilton-Jacobi theorem for Hamiltonian system, see Cariñena et al [5, 6]. Moreover, note that Theorem 1.1 is also generalized in the context of time-dependent Hamiltonian system by Marsden and Ratiu in [19], and the Hamilton-Jacobi equation may be regarded as a nonlinear partial differential equation for some generating function \( S \). Thus, the problem is become how to choose a time-dependent canonical transformation \( \Psi : T^*Q \times \mathbb{R} \to T^*Q \times \mathbb{R} \), which transforms the dynamical vector field of a time-dependent Hamiltonian system to equilibrium, such that the generating function \( S \) of \( \Psi \) satisfies the time-dependent Hamilton-Jacobi equation. In particular, for the time-independent Hamiltonian system, ones may look for a symplectic map as the canonical transformation. This work offers an important idea that one can use the dynamical vector field of a Hamiltonian system to describe Hamilton-Jacobi equation. In consequence, if assume that \( \gamma : Q \to T^*Q \) is a closed one-form on \( Q \), and define that \( X^\gamma_H = T\pi_Q \cdot X_H \cdot \gamma \), where \( X_H \) is the dynamical vector field of Hamiltonian system \((T^*Q, \omega, H)\), then the fact that \( X^\gamma_H \) and \( X_H \) are \( \gamma \)-related, that is, \( T\gamma \cdot X^\gamma_H = X_H \cdot \gamma \) is equivalent that \( d(H \cdot \gamma) = 0 \), which is given in Cariñena et al [5, 6]. Motivated by the above research work, Wang in [28] prove an important lemma, which is a modification for the corresponding result of Abraham and Marsden in [1], such that we can derive precisely the geometric constraint conditions of the regular reduced symplectic forms for the dynamical vector fields of a regular reducible Hamiltonian system on the cotangent bundle of a configuration manifold, which are called
the Type I and Type II of Hamilton-Jacobi equation, because they are the development of the above classical Hamilton-Jacobi equation given by Theorem 1.1, see Abraham and Marsden [1] and Wang [28]. Moreover, León and Wang in [14] generalize the above results to the nonholonomic Hamiltonian system and the nonholonomic reducible Hamiltonian system on a cotangent bundle, by using the distributional Hamiltonian system and the reduced distributional Hamiltonian system.

In order to describe the impact of different geometric structures and constraints for the dynamics of a Hamiltonian system, in the following we first consider the magnetic Hamiltonian system. Define a magnetic symplectic form \( \omega^B = \omega - \pi_Q^*B \), and the \( \pi_Q^*B \) is called a magnetic term on \( T^*Q \), where \( \omega \) is the usual canonical symplectic form on \( T^*Q \), and \( B \) is the closed two-form on \( Q \), and the map \( \pi_Q^*: T^*Q \rightarrow T^*T^*Q \). A magnetic Hamiltonian system is a Hamiltonian system defined by the magnetic symplectic form, which is a canonical Hamiltonian system coupling the action of a magnetic field \( B \). Under the impact of magnetic term \( \pi_Q^*B \), the magnetic symplectic form \( \omega^B \), in general, is not the canonical symplectic form on \( T^*Q \), we cannot prove the Hamilton-Jacobi theorem for the magnetic Hamiltonian system just like same as the above Theorem 1.1. We have to look for a new way. In this paper, we first drive precisely the geometric constraint conditions of magnetic symplectic form for the magnetic Hamiltonian vector field. These conditions are called the Type I and Type II of Hamilton-Jacobi equation, which are the development of the Type I and Type II of Hamilton-Jacobi equation for a Hamiltonian system given in Wang [28].

Next, we consider the magnetic Hamiltonian system with nonholonomic constraint, which is called the nonholonomic magnetic Hamiltonian system. In mechanics, it is very often that many systems have constraints, and usually, under the restriction given by nonholonomic constraint, in general, the dynamical vector field of a nonholonomic magnetic Hamiltonian system may not be Hamiltonian. Thus, we can not describe the Hamilton-Jacobi equations for nonholonomic magnetic Hamiltonian system from the viewpoint of generating function as in the classical Hamiltonian case, that is, we cannot prove the Hamilton-Jacobi theorem for the nonholonomic magnetic Hamiltonian system, just like same as the above Theorem 1.1. In this paper, by analyzing carefully the structure for the nonholonomic dynamical vector field, we first give a geometric formulation of the distributional magnetic Hamiltonian system for the nonholonomic magnetic Hamiltonian system, which is determined by a non-degenerate distributional two-form induced from the magnetic symplectic form. The distributional magnetic Hamiltonian system is not Hamiltonian, however, it is a dynamical system closely related to a magnetic Hamiltonian system. Then we drive precisely two types of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system, which are the development of the Type I and Type II of Hamilton-Jacobi equation for a distributional Hamiltonian system given in León and Wang [14].

Thirdly, it is a natural problem to consider the nonholonomic magnetic Hamiltonian system with symmetry. In this paper, we generalize the above results to nonholonomic reducible magnetic Hamiltonian system with symmetry. By using the method of nonholonomic reduction given in Bates and Śniatycki [3], and analyzing carefully the structure for the nonholonomic reduced dynamical vector field, we first give a geometric formulation of the nonholonomic reduced distributional magnetic Hamiltonian system. Since the nonholonomic reduced distributional magnetic Hamiltonian system is not yet Hamiltonian, but, it is a dynamical system closely related to a magnetic Hamiltonian system. Then we can derive precisely the geometric constraint conditions of the non-degenerate, and nonholonomic reduced distributional two-form for the nonholonomic reducible dynamical vector field, that is, the two types of Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system. These research work reveal the deeply internal relationships of the magnetic symplectic structure, nonholonomic constraint, the induced (resp. reduced) distributional two-forms, and the dynamical vector fields of the nonholonomic magnetic system.
Hamiltonian system.

The paper is organized as follows. In section 2 we first give some definitions and basic facts about the magnetic Hamiltonian system, the nonholonomic constraint, the nonholonomic magnetic Hamiltonian system and the distributional magnetic Hamiltonian system, which will be used in subsequent sections. In section 3, for a magnetic Hamiltonian system defined by a magnetic symplectic form, we first drive precisely the geometric constraint conditions of magnetic symplectic form for the magnetic Hamiltonian vector field, which are called the Type I and Type II of Hamilton-Jacobi equation. In section 4, we derive two types of Hamilton-Jacobi equation for a distributional magnetic Hamiltonian system, by the analysis and calculation in detail. The nonholonomic reducible magnetic Hamiltonian system with symmetry is considered in section 5, and derive precisely the geometric constraint conditions of the non-degenerate, and nonholonomic reduced distributional two-form for the nonholonomic reducible dynamical vector field, that is, the two types of Hamilton-Jacobi equations for the nonholonomic reduced distributional magnetic Hamiltonian system. These research work develop Hamilton-Jacobi theory for the nonholonomic magnetic Hamiltonian system, as well as with symmetry, and make us have much deeper understanding and recognition for the structures of the nonholonomic magnetic Hamiltonian systems.

2 Nonholonomic Magnetic Hamiltonian System

In this section we first give some definitions and basic facts about the magnetic Hamiltonian system, the nonholonomic constraint and the nonholonomic magnetic Hamiltonian system. Moreover, by analyzing carefully the structure for the nonholonomic dynamical vector field, we give a geometric formulation of distributional magnetic Hamiltonian system, which is determined by a non-degenerate distributional two-form induced from the magnetic symplectic form. All of them will be used in subsequent sections.

Let $Q$ be an $n$-dimensional smooth manifold and $TQ$ the tangent bundle, $T^*Q$ the cotangent bundle with a canonical symplectic form $\omega$ and the projection $\pi_Q : T^*Q \rightarrow Q$ induces the map $\pi^*_Q : T^*Q \rightarrow T^*T^*Q$. We consider the magnetic symplectic form $\omega^B = \omega - \pi^*_Q B$, where $\omega$ is the canonical symplectic form on $T^*Q$, and $B$ is the closed two-form on $Q$, and the $\pi^*_Q B$ is called a magnetic term on $T^*Q$. A magnetic Hamiltonian system is a triple $(T^*Q, \omega^B, H)$, which is a Hamiltonian system defined by the magnetic symplectic form $\omega^B$, that is, a canonical Hamiltonian system coupling the action of a magnetic field $B$. For a given Hamiltonian $H$, the dynamical vector field $X^B_H$, which is called the magnetic Hamiltonian vector field, satisfies the magnetic Hamilton’s equation, that is, $i_{X^B_H} \omega^B = dH$. In canonical cotangent bundle coordinates, for any $q \in Q, (q, p) \in T^*Q$, we have that

$$
\omega = \sum_{i=1}^n dq^i \wedge dp_i, \quad B = \sum_{i,j=1}^n B_{ij} dq^i \wedge dq^j, \quad dB = 0,
$$

$$
\omega^B = \omega - \pi^*_Q B = \sum_{i=1}^n dq^i \wedge dp_i - \sum_{i,j=1}^n B_{ij} dq^i \wedge dq^j,
$$

and the magnetic Hamiltonian vector field $X^B_H$ with respect to the magnetic symplectic form $\omega^B$ can be expressed that

$$
X^B_H = \sum_{i=1}^n \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} - \frac{\partial H}{\partial q^i} \frac{\partial}{\partial p_i} \right) - \sum_{i,j=1}^n B_{ij} \frac{\partial H}{\partial p_j} \frac{\partial}{\partial p_i}.
$$

See Marsden et al. [17].
In order to describe the nonholonomic magnetic Hamiltonian system, in the following we first give the completeness and regularity conditions for nonholonomic constraints of a mechanical system, see León and Wang \[14\]. In fact, in order to describe the dynamics of a nonholonomic mechanical system, we need some restriction conditions for nonholonomic constraints of the system. At first, we note that the set of Hamiltonian vector fields forms a Lie algebra with respect to the Lie bracket, since \( X_{\{f,g\}} = -[X_f, X_g] \). But, the Lie bracket operator, in general, may not be closed on the restriction of a nonholonomic constraint. Thus, we have to give the following completeness condition for nonholonomic constraints of a system.

**D-completeness** Let \( Q \) be a smooth manifold and \( TQ \) its tangent bundle. A distribution \( D \subset TQ \) is said to be completely nonholonomic (or bracket-generating) if \( D \) along with all of its iterated Lie brackets \([D, D],[D, [D, D]], \ldots\) spans the tangent bundle \( TQ \). Moreover, we consider a nonholonomic mechanical system on \( Q \), which is given by a Lagrangian function \( L : TQ \to \mathbb{R} \) subject to constraints determined by a nonholonomic distribution \( D \subset TQ \) on the configuration manifold \( Q \). Then the nonholonomic system is said to be completely nonholonomic, if the distribution \( D \subset TQ \) determined by the nonholonomic constraints is completely nonholonomic.

**D-regularity** In the following we always assume that \( Q \) is a smooth manifold with coordinates \((q^i)\), and \( TQ \) its tangent bundle with coordinates \((q^i, \dot{q}^i)\), and \( T^*Q \) its cotangent bundle with coordinates \((q^i, p_j)\), which are the canonical cotangent coordinates of \( T^*Q \) and \( \omega = dq^i \wedge dp_i \) is canonical symplectic form on \( T^*Q \). If the Lagrangian \( L : TQ \to \mathbb{R} \) is hyperregular, that is, the Hessian matrix \((\partial^2 L/\partial q^i \partial \dot{q}^j)\) is nondegenerate everywhere, then the Legendre transformation \( FL : TQ \to T^*Q \) is a diffeomorphism. In this case the Hamiltonian \( H : T^*Q \to \mathbb{R} \) is given by \( H(q, p) = \dot{q} \cdot p - L(q, \dot{q}) \) with Hamiltonian vector field \( X_H \), which is defined by the Hamilton’s equation \( i_{X_H} \omega = \mathbf{d}H \), and \( M = FL(D) \) is a constraint submanifold in \( T^*Q \). In particular, for the nonholonomic constraint \( D \subset TQ \), the Lagrangian \( L \) is said to be \( D \)-regular, if the restriction of Hessian matrix \((\partial^2 L/\partial q^i \partial \dot{q}^j)\) on \( D \) is nondegenerate everywhere. Moreover, a nonholonomic system is said to be \( D \)-regular, if its Lagrangian \( L \) is \( D \)-regular. Note that the restriction of a positive definite symmetric bilinear form to a subspace is also positive definite, and hence nondegenerate. Thus, for a simple nonholonomic mechanical system, that is, whose Lagrangian is the total kinetic energy minus potential energy, it is \( D \)-regular automatically.

A nonholonomic magnetic Hamiltonian system is a 4-tuple \((T^*Q, \omega^B, D, H)\), which is a magnetic Hamiltonian system with a \( D \)-completely and \( D \)-regularly nonholonomic constraint \( D \subset TQ \). Under the restriction given by constraint, in general, the dynamical vector field of a nonholonomic magnetic Hamiltonian system may not be magnetic Hamiltonian, however the system is a dynamical system closely related to a magnetic Hamiltonian system. In the following we shall derive a distributional magnetic Hamiltonian system of the nonholonomic magnetic Hamiltonian system \((T^*Q, \omega^B, D, H)\), by analyzing carefully the structure for the nonholonomic dynamical vector field similar to the method in León and Wang \[14\]. It is worthy of noting that the leading distributional Hamiltonian system is also called a semi-Hamiltonian system in Patric \[23\].

We consider that the constraint submanifold \( M = FL(D) \subset T^*Q \) and \( i_M : M \to T^*Q \) the inclusion, the symplectic form \( \omega^M_B = i_M^*\omega^B \) is induced from the magnetic symplectic form \( \omega^B \) on \( T^*Q \). We define the distribution \( \mathcal{F} \) as the pre-image of the nonholonomic constraints \( D \) for the map \( T\pi_Q : TT^*Q \to TQ \), that is, \( \mathcal{F} = (T\pi_Q)^{-1}(D) \subset TT^*Q \), which is a distribution along \( M \), and \( \mathcal{F}^\circ := \{ \alpha \in T^*T^*Q | \alpha, v > 0, \forall v \in TT^*Q \} \) is the annihilator of \( \mathcal{F} \) in \( T^*T^*Q|_M \). We consider the following nonholonomic constraints condition

\[
(i_X \omega^B - dH) \in \mathcal{F}^\circ, \quad X \in TM,
\]  \[2.1\]
From Cantrijn et al. [4], we know that there exists an unique nonholonomic vector field $X_n$ satisfying the above condition (2.1), if the admissibility condition $\dim \mathcal{M} = \text{rank} \mathcal{F}$ and the compatibility condition $T\mathcal{M} \cap \mathcal{F}^\perp = \{0\}$ hold, where $\mathcal{F}^\perp$ denotes the magnetic symplectic orthogonal of $\mathcal{F}$ with respect to the magnetic symplectic form $\omega^B$ on $T^*Q$. In particular, when we consider the Whitney sum decomposition $T(T^*Q)|_\mathcal{M} = T\mathcal{M} \oplus \mathcal{F}^\perp$ and the canonical projection $P : T(T^*Q)|_\mathcal{M} \to T\mathcal{M}$, then we have that $X_n = P(X^B_H)$.

From the condition (2.1) we know that the nonholonomic vector field, in general, may not be magnetic Hamiltonian, because of the restriction of nonholonomic constraints. But, we hope to study the dynamical vector field of nonholonomic magnetic Hamiltonian system by using the similar method of studying magnetic Hamiltonian vector field. From León and Wang [14] and Bates and Śniatycki [3], by using the similar method, we can define the distribution $\mathcal{K} = \mathcal{F} \cap T\mathcal{M}$, and $\mathcal{K}^\perp = \mathcal{F}^\perp \cap T\mathcal{M}$, where $\mathcal{K}^\perp$ denotes the magnetic symplectic orthogonal of $\mathcal{K}$ with respect to the magnetic symplectic form $\omega^B$, and the admissibility condition $\dim \mathcal{M} = \text{rank} \mathcal{F}$ and the compatibility condition $T\mathcal{M} \cap \mathcal{F}^\perp = \{0\}$ hold, then we know that the restriction of the symplectic form $\omega^B_M$ on $T^*\mathcal{M}$ fibrewise to the distribution $\mathcal{K}$, that is, $\omega^B_\mathcal{K} = \tau_\mathcal{K} \cdot \omega^B_M$ is non-degenerate, where $\tau_\mathcal{K}$ is the restriction map to distribution $\mathcal{K}$. It is worthy of noting that $\omega^B_\mathcal{K}$ is not a true two-form on a manifold, so it does not make sense to speak about it being closed. We call $\omega^B_\mathcal{K}$ as a distributional two-form to avoid any confusion. Because $\omega^B_\mathcal{K}$ is non-degenerate as a bilinear form on each fibre of $\mathcal{K}$, there exists a vector field $X^B_\mathcal{K}$ on $\mathcal{M}$ which takes values in the constraint distribution $\mathcal{K}$, such that the distributional magnetic Hamiltonian equation

$$i_{X^B_\mathcal{K}}\omega^B_\mathcal{K} = dH_\mathcal{K} \tag{2.2}$$

holds, where $dH_\mathcal{K}$ is the restriction of $dH_\mathcal{M}$ to $\mathcal{K}$, and the function $H_\mathcal{K}$ satisfies $dH_\mathcal{K} = \tau_\mathcal{K} \cdot dH_\mathcal{M}$, and $H_\mathcal{M} = \tau_\mathcal{M} \cdot H$ is the restriction of $H$ to $\mathcal{M}$. Moreover, from the distributional magnetic Hamiltonian equation (2.2), we have that $X^B_\mathcal{K} = \tau_\mathcal{K} \cdot X^B_H$. Then the triple $(\mathcal{K}, \omega^B_\mathcal{K}, H_\mathcal{K})$ is a distributional magnetic Hamiltonian system of the nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, \mathcal{D}, H)$. Thus, the geometric formulation of the distributional magnetic Hamiltonian system may be summarized as follows.

**Definition 2.1** *(Distributional Magnetic Hamiltonian System)* Assume that the 4-tuple $(T^*Q, \omega^B, \mathcal{D}, H)$ is a $\mathcal{D}$-completely and $\mathcal{D}$-regularly nonholonomic magnetic Hamiltonian system, where the magnetic symplectic form $\omega^B = \omega - \pi^B_M B$ on $T^*Q$, and $\omega$ is the canonical symplectic form on $T^*Q$ and $B$ is a closed two-form on $Q$, and $\mathcal{D} \subset TQ$ is a $\mathcal{D}$-completely and $\mathcal{D}$-regularly nonholonomic constraint of the system. If there exist a distribution $\mathcal{K}$, an associated non-degenerate distributional two-form $\omega^B_\mathcal{K}$ induced by the magnetic symplectic form $\omega^B$ and a vector field $X^B_\mathcal{K}$ on the constraint submanifold $\mathcal{M} = F_L(\mathcal{D}) \subset T^*Q$, such that the distributional magnetic Hamiltonian equation $i_{X^B_\mathcal{K}}\omega^B_\mathcal{K} = dH_\mathcal{K}$ holds, where $dH_\mathcal{K}$ is the restriction of $dH_\mathcal{M}$ to $\mathcal{K}$ and the function $H_\mathcal{K}$ satisfies $dH_\mathcal{K} = \tau_\mathcal{K} \cdot dH_\mathcal{M}$ as defined above, then the triple $(\mathcal{K}, \omega^B_\mathcal{K}, H_\mathcal{K})$ is called a distributional magnetic Hamiltonian system of the nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, \mathcal{D}, H)$, and $X^B_\mathcal{K}$ is called a nonholonomic dynamical vector field of the distributional magnetic Hamiltonian system $(\mathcal{K}, \omega^B_\mathcal{K}, H_\mathcal{K})$. Under the above circumstances, we refer to $(T^*Q, \omega^B, \mathcal{D}, H)$ as a nonholonomic magnetic Hamiltonian system with an associated distributional magnetic Hamiltonian system $(\mathcal{K}, \omega^B_\mathcal{K}, H_\mathcal{K})$.

Moreover, in section 5, we consider the nonholonomic magnetic Hamiltonian system with symmetry. By using the similar method for nonholonomic reduction given in Bates and Śniatycki [3] and León and Wang [14], and analyzing carefully the structure for the nonholonomic reduced dynamical vector field, we also give a geometric formulation of the nonholonomic reduced distributional magnetic Hamiltonian system.
3 Hamilton-Jacobi Equation of Magnetic Hamiltonian System

In order to describe the impact of different geometric structures and constraints for the Hamilton-Jacobi theory, in this paper, we shall give two types of Hamilton-Jacobi equations for the magnetic Hamiltonian system, the distributional magnetic Hamiltonian system and the nonholonomic reduced distributional magnetic Hamiltonian system.

In this section, we first derive precisely the geometric constraint conditions of the magnetic symplectic form for the dynamical vector field of a magnetic Hamiltonian system, that is, Type I and Type II of Hamilton-Jacobi equation for the magnetic Hamiltonian system. In order to do this, in the following we first give some important notions and prove a key lemma, which is an important tool for the proofs of two types of Hamilton-Jacobi theorem for the magnetic Hamiltonian system.

Denote by $\Omega^i(Q)$ the set of all $i$-forms on $Q$, $i = 1, 2$. For any $\gamma \in \Omega^1(Q)$, $q \in Q$, then $\gamma(q) \in T_q^*Q$, and we can define a map $\gamma : Q \to T^*Q$, $q \to (q, \gamma(q))$. Hence we say often that the map $\gamma : Q \to T^*Q$ is an one-form on $Q$. If the one-form $\gamma$ is closed, then $d\gamma(x, y) = 0$, $\forall x, y \in TQ$. Note that for any $v, w \in TT^*Q$, we have that $d\gamma(T\pi_Q(v), T\pi_Q(w)) = \pi^*(d\gamma)(v, w)$ is a two-form on the cotangent bundle $T^*Q$, where $\pi^* : T^*Q \to T^*T^*Q$. Thus, in the following we can give a weaker notion.

**Definition 3.1** The one-form $\gamma$ is called to be closed with respect to $T\pi_Q : TT^*Q \to TQ$, if for any $v, w \in TT^*Q$, we have that $d\gamma(T\pi_Q(v), T\pi_Q(w)) = 0$.

For the one-form $\gamma : Q \to T^*Q$, $d\gamma$ is a two-form on $Q$. Assume that $B$ is a closed two-form on $Q$, we say that the $\gamma$ satisfies condition $d\gamma = -B$, if for any $x, y \in TQ$, we have that $(d\gamma + B)(x, y) = 0$. In the following we can give a new notion.

**Definition 3.2** Assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$, we say that the $\gamma$ satisfies condition that $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$, if for any $v, w \in TT^*Q$, we have that $(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0$.

From the above definition we know that, if $\gamma$ satisfies condition $d\gamma = -B$, then it must satisfy condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$. Conversely, if $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$, then it may not satisfy condition $d\gamma = -B$. We can prove a general result as follows, which states that the notion that $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$, is not equivalent to the notion that $\gamma$ satisfies condition $d\gamma = -B$.

**Proposition 3.3** Assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$ and it doesn’t satisfy condition $d\gamma = -B$. We define the set $N$, which is a subset of $TQ$, such that the one-form $\gamma$ on $N$ satisfies the condition that for any $x, y \in N$, $(d\gamma + B)(x, y) \neq 0$. Denote by $Ker(T\pi_Q) = \{u \in TT^*Q \mid T\pi_Q(u) = 0\}$, and $T\gamma : TQ \to TT^*Q$ is the tangent map of $\gamma : Q \to T^*Q$. If $T\gamma(N) \subset Ker(T\pi_Q)$, then $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$.

**Proof:** In fact, for any $v, w \in TT^*Q$, if $T\pi_Q(v) \notin N$, or $T\pi_Q(w) \notin N$, then by the definition of $N$, we know that $(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0$; if $T\pi_Q(v) \in N$, and $T\pi_Q(w) \in N$, from the condition $T\gamma(N) \subset Ker(T\pi_Q)$, we know that $T\pi_Q : T\gamma \cdot T\pi_Q(v) = T\pi_Q(v) = 0$, and $T\pi_Q \cdot T\gamma : T\pi_Q(w) = T\pi_Q(w) = 0$, where we have used the relation $\pi_Q \cdot \gamma \cdot \pi_Q = \pi_Q$, and hence $(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0$. Thus, for any $v, w \in TT^*Q$, we have always that $(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0$, that is, $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$. ■
From the above Definition 3.1 and Definition 3.2, we know that, when $B = 0$, the notion that, $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T \pi_Q : TT^*Q \to TQ$, become the notion that $\gamma$ is closed with respect to $T \pi_Q : TT^*Q \to TQ$. Now, we can prove the following lemma, which is a generalization of a corresponding to lemma given by Wang [28], and the lemma is a very important tool for our research.

**Lemma 3.4** Assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$, and $\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q$. For the magnetic symplectic form $\omega^B = \omega - \pi_Q B$ on $T^*Q$, where $\omega$ is the canonical symplectic form on $T^*Q$, and $B$ is a closed two-form on $Q$, then we have that the following two assertions hold.

(i) For any $v, w \in TT^*Q$, $\lambda^* \omega^B(v, w) = -(d\gamma + B)(T \pi_Q(v), T \pi_Q(w))$;

(ii) For any $v, w \in TT^*Q$, $\omega^B(T \lambda \cdot v, w) = \omega^B(v, w - T \lambda \cdot w) - (d\gamma + B)(T \pi_Q(v), T \pi_Q(w))$.

**Proof:** We first prove the assertion (i). Since $\omega$ is the canonical symplectic form on $T^*Q$, we know that there is an unique canonical one-form $\theta$, such that $\omega = -d\theta$. From the Proposition 3.2.11 in Abraham and Marsden [1], we have that for the one-form $\gamma : Q \to T^*Q$, $\gamma^* \theta = \gamma$. Then we can obtain that for any $x, y \in TQ$,

$$\gamma^* \omega(x, y) = \gamma^*(-d\theta)(x, y) = -d(\gamma^* \theta)(x, y) = -d\gamma(x, y).$$

Note that $\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q$, and $\lambda^* = \pi_Q^* \cdot \gamma^* : T^*T^*Q \to T^*T^*Q$, then we have that for any $v, w \in TT^*Q$,

$$\lambda^* \omega(v, w) = \lambda^*(-d\theta)(v, w) = -d(\lambda^* \theta)(v, w) = -d(\pi_Q^* \cdot \gamma^* \theta)(v, w) = -d(\pi_Q^* \cdot \gamma)(v, w) = -d\gamma(T \pi_Q(v), T \pi_Q(w)).$$

Hence, we have that

$$\lambda^* \omega^B(v, w) = \lambda^* \omega(v, w) - \lambda^* \cdot \pi_Q^* B(v, w) = -d\gamma(T \pi_Q(v), T \pi_Q(w)) - (\pi_Q \cdot \gamma \cdot \pi_Q)^* B(v, w) = -d\gamma(T \pi_Q(v), T \pi_Q(w)) - \pi_Q B(v, w) = -(d\gamma + B)(T \pi_Q(v), T \pi_Q(w)),$$

where we have used the relation $\pi_Q \cdot \gamma \cdot \pi_Q = \pi_Q$. It follows that the assertion (i) holds.

Next, we prove the assertion (ii). For any $v, w \in TT^*Q$, note that $v - T(\gamma \cdot \pi_Q) \cdot v$ is vertical, because

$$T \pi_Q(v - T(\gamma \cdot \pi_Q) \cdot v) = T \pi_Q(v) - T(\pi_Q \cdot \gamma \cdot \pi_Q) \cdot v = T \pi_Q(v) - T \pi_Q(v) = 0,$$

Thus, $\omega(v - T(\gamma \cdot \pi_Q) \cdot v, w - T(\gamma \cdot \pi_Q) \cdot w) = 0$, and hence,

$$\omega(T(\gamma \cdot \pi_Q) \cdot v, w) = \omega(v, w - T(\gamma \cdot \pi_Q) \cdot w) + \omega(T(\gamma \cdot \pi_Q) \cdot v, T(\gamma \cdot \pi_Q) \cdot w).$$

However, the second term on the right-hand side is given by

$$\omega(T(\gamma \cdot \pi_Q) \cdot v, T(\gamma \cdot \pi_Q) \cdot w) = \gamma^* \omega(T \pi_Q(v), T \pi_Q(w)) = -d\gamma(T \pi_Q(v), T \pi_Q(w)),$$

It follows that

$$\omega(T \lambda \cdot v, w) = \omega(T(\gamma \cdot \pi_Q) \cdot v, w) = \omega(v, w - T(\gamma \cdot \pi_Q) \cdot w) - d\gamma(T \pi_Q(v), T \pi_Q(w)) = \omega(v, w - T \lambda \cdot w) - d\gamma(T \pi_Q(v), T \pi_Q(w)).$$
Hence, we have that
\[
\omega^B(T\lambda \cdot v, w) = \omega(T\lambda \cdot v, w) - \pi^*_Q B(T\lambda \cdot v, w)
\]
\[
= \omega(v, w - T\lambda \cdot w) - d\gamma(T\pi_Q(v), T\pi_Q(w)) - B(T\pi_Q \cdot T\lambda \cdot v, T\pi_Q(w))
\]
\[
= \omega^B(v, w - T\lambda \cdot w) + \pi^*_Q B(v, w - T\lambda \cdot w)
\]
\[
- d\gamma(T\pi_Q(v), T\pi_Q(w)) - B(T\pi_Q \cdot \lambda \cdot v, T\pi_Q(w))
\]
\[
= \omega^B(v, w - T\lambda \cdot w) + \pi^*_Q B(v, w - B(T\pi_Q(v), T\pi_Q(w), T\pi_Q(w))
\]
\[
= \omega^B(v, w - T\lambda \cdot w) + \pi^*_Q B(v, w - B(T\pi_Q(v), T\pi_Q(w)) - (d\gamma + B)(T\pi_Q(v), T\pi_Q(w))
\]
\[
= \omega^B(v, w - T\lambda \cdot w) - (d\gamma + B)(T\pi_Q(v), T\pi_Q(w)).
\]

Thus, the assertion (ii) holds.

Since a magnetic Hamiltonian system is a Hamiltonian system defined by the magnetic symplectic form, and it is a canonical Hamiltonian system coupling the action of a magnetic field \(B\). Usually, under the impact of magnetic term \(\omega\) in general, is not the canonical symplectic form, \(\omega\) is the dynamical vector field of the magnetic Hamiltonian system, that is, Type I and Type II of Hamilton-Jacobi equation for the magnetic Hamiltonian system. At first, for a given magnetic Hamiltonian system \((T^*Q, \omega^B, H)\) on \(T^*Q\), by using the above Lemma 3.4, magnetic symplectic form \(\omega^B\) and the magnetic Hamiltonian vector field \(X^B_H\), we can derive precisely the following type I of Hamilton-Jacobi equation for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\).

**Theorem 3.5 (Type I of Hamilton-Jacobi Theorem for a Magnetic Hamiltonian System)** For a given magnetic Hamiltonian system \((T^*Q, \omega^B, H)\) with the magnetic symplectic form \(\omega^B = \omega - \pi^*_Q B\) on \(T^*Q\), where \(\omega\) is the canonical symplectic form on \(T^*Q\) and \(B\) is a closed two-form on \(Q\), assume that \(\gamma : Q \to T^*Q\) is an one-form on \(Q\), and \(X^\gamma = T\pi_Q \cdot X^B_H \cdot \gamma\), where \(X^B_H\) is the dynamical vector field of the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\), that is, the magnetic Hamiltonian vector field. If the one-form \(\gamma : Q \to T^*Q\) satisfies the condition that \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\), then \(\gamma\) is a solution of the equation \(T\gamma \cdot X^\gamma = X^B_H \cdot \gamma\). The equation is called the Type I of Hamilton-Jacobi equation for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\). Here the maps involved in the theorem are shown in the following Diagram-1.

\[
\begin{array}{cccc}
T^*Q & \xrightarrow{\pi_Q} & Q & \xrightarrow{\gamma} & T^*Q \\
& \xleftarrow{T\pi_Q} & TQ & \xleftarrow{T\gamma} & T^*Q \\
T(T^*Q) & \xrightarrow{T\pi_Q} & TQ & \xleftarrow{T\gamma} & T(T^*Q)
\end{array}
\]

**Diagram-1**

**Proof:** If we take that \(v = X^B_H \cdot \gamma \in TT^*Q\), and for any \(w \in TT^*Q\), \(T\pi_Q(w) \neq 0\), from Lemma 3.4(ii) and \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\), that is, \((d\gamma + B)(T\pi_Q \cdot X^B_H \cdot \gamma, T\pi_Q \cdot w) = 0\),
we have that
\[
\omega^B(T\gamma \cdot X^\gamma, w) = \omega^B(T\gamma \cdot T\pi_Q \cdot X^B_H \cdot \gamma, w) = \omega^B(T(\gamma \cdot \pi_Q) \cdot X^B_H \cdot \gamma, w)
\]
\[
= \omega^B(X^B_H \cdot \gamma, w - T(\gamma \cdot \pi_Q) \cdot w) - (d\gamma + B)(T\pi_Q \cdot X^B_H \cdot \gamma, T\pi_Q \cdot w)
\]
\[
= \omega^B(X^B_H \cdot \gamma, w) - \omega^B(X^B_H \cdot \gamma, T\lambda \cdot w).
\]
Hence, we have that
\[
\omega^B(T\gamma \cdot X^\gamma, w) - \omega^B(X^B_H \cdot \gamma, w) = -\omega^B(X^B_H \cdot \gamma, T\lambda \cdot w).
\]
(3.1)

If \(\gamma\) satisfies the equation \(T\gamma \cdot X^\gamma = X^B_H \cdot \gamma\), from Lemma 3.4(i) we know that the right side of (3.1) becomes that
\[
\omega^B(X^B_H \cdot \gamma, T\lambda \cdot w) = \omega^B(T\gamma \cdot X^\gamma, T\lambda \cdot w)
\]
\[
= \omega^B(T\gamma \cdot T\pi_Q \cdot X^B_H \cdot \gamma, T\lambda \cdot w)
\]
\[
= \omega^B(T\lambda \cdot X^B_H \cdot \gamma, T\lambda \cdot w)
\]
\[
= \lambda^*\omega^B(X^B_H \cdot \gamma, w)
\]
\[
= -(d\gamma + B)(T\pi_Q \cdot X^B_H \cdot \gamma, T\pi_Q \cdot w) = 0,
\]
since \(\gamma : Q \to T^*Q\) satisfies the condition that \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\). But, because the magnetic symplectic form \(\omega^B\) is non-degenerate, the left side of (3.1) equals zero, only when \(\gamma\) satisfies the equation \(T\gamma \cdot X^\gamma = X^B_H \cdot \gamma\). Thus, if the one-form \(\gamma : Q \to T^*Q\) satisfies the condition that \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\), then \(\gamma\) must be a solution of the Type I of Hamilton-Jacobi equation \(T\gamma \cdot X^\gamma = X^B_H \cdot \gamma\), for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\).

It is worthy of noting that, when \(B = 0\), in this case the magnetic symplectic form \(\omega^B\) is just the canonical symplectic form \(\omega\) on \(T^*Q\), and the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\) becomes the Hamiltonian system \((T^*Q, \omega, H)\) with the canonical symplectic form \(\omega\), and the condition that the one-form \(\gamma : Q \to T^*Q\) satisfies the condition, \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\), becomes the condition that \(\gamma\) is closed with respect to \(T\pi_Q : TT^*Q \to TQ\). Thus, from above Theorem 3.5, we can obtain Theorem 2.5 in Wang [28], that is, the Type I of Hamilton-Jacobi theorem for a Hamiltonian system. On the other hand, from the proof of Theorem 2.5 in Wang [28], we know that if an one-form \(\gamma : Q \to T^*Q\) is not closed on \(Q\) with respect to \(T\pi_Q : TT^*Q \to TQ\), then \(\gamma\) is not a solution of the Type I of Hamilton-Jacobi equation \(\gamma \cdot X^\gamma = X^B_H \cdot \gamma\). But, note that, if \(\gamma : Q \to T^*Q\) is not closed on \(Q\) with respect to \(T\pi_Q : TT^*Q \to TQ\), that is, there exist \(v, w \in TT^*Q\), such that \(d\gamma(T\pi_Q(v), T\pi_Q(w)) \neq 0\), and hence \(\gamma\) is not yet closed on \(Q\). However, because \(d \cdot d\gamma = d^2\gamma = 0\), and hence the \(d\gamma\) is a closed two-form on \(Q\). Thus, we can construct a magnetic symplectic form on \(T^*Q\), that is, \(\omega^B = \omega + \pi^*_Q(d\gamma) = \omega - \pi^*_QB\), where \(B = -d\gamma\), and \(\omega\) is the canonical symplectic form on \(T^*Q\), and \(\pi^*_Q : T^*Q \to T^*T^*Q\). Moreover, we hope to look for a new magnetic Hamiltonian system, such that \(\gamma\) is a solution of the Type I of Hamilton-Jacobi equation for the new magnetic Hamiltonian system. In fact, for a given Hamiltonian system \((T^*Q, \omega, H)\) with the canonical symplectic form \(\omega\) on \(T^*Q\), and \(\gamma : Q \to T^*Q\) is an one-form on \(Q\), and it is not closed with respect to \(T\pi_Q : TT^*Q \to TQ\). Then we can construct a magnetic symplectic form on \(T^*Q\), \(\omega^B = \omega + \pi^*_Q(d\gamma)\), where \(B = -d\gamma\), and a magnetic Hamiltonian system \((T^*Q, \omega^B, H)\), its dynamical vector field is given by \(X^B_H\), which satisfies the magnetic Hamiltonian equation, that is, \(i_{X^B_H}\omega^B = dH\). In this case, for any \(x, y \in TQ\), we have that \((d\gamma + B)(x, y) = 0\), and hence for any \(v, w \in TT^*Q\), we have \((d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0\), that is, the one-form \(\gamma : Q \to T^*Q\) satisfies the condition, \(d\gamma = -B\) with respect to \(T\pi_Q : TT^*Q \to TQ\). Thus, by using Lemma 3.4 and the magnetic Hamiltonian vector field \(X^B_H\), from Theorem 3.5 we can obtain the following Theorem 3.6.
Theorem 3.6 For a given Hamiltonian system \((T^*Q, \omega, H)\) with the canonical symplectic form \(\omega\) on \(T^*Q\), and assume that the one-form \(\gamma : Q \to T^*Q\) is not closed with respect to \(T\pi_Q : TT^*Q \to TQ\). Then one can construct a magnetic symplectic form on \(T^*Q\), that is, \(\omega^B = \omega + \pi_Q(d\gamma)\), where \(B = -d\gamma\), and a magnetic Hamiltonian system \((T^*Q, \omega^B, H)\). Denote \(X^\gamma = T\pi_Q \cdot X^B_H \cdot \gamma\), where \(X^B_H\) is the dynamical vector field of the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\). Then \(\gamma\) is a solution of the Type I of Hamilton-Jacobi equation \(T\gamma \cdot X^\gamma = X^B_H \cdot \gamma\), for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\).

Next, for any symplectic map \(\varepsilon : T^*Q \to T^*Q\) with respect to the magnetic symplectic form \(\omega^B\), we can derive precisely the following Type II of Hamilton-Jacobi equation for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\). For convenience, the maps involved in the following theorem and its proof are shown in Diagram-2.

\[
\begin{aligned}
T^*Q &\xrightarrow{\varepsilon} T^*Q \xrightarrow{T\pi_Q} Q \xrightarrow{\gamma} T^*Q \\
&\xrightarrow{X^B_H} T(T^*Q) \xrightarrow{T\gamma} TQ \xrightarrow{T\pi_Q} T(T^*Q)
\end{aligned}
\]

Diagram-2

**Theorem 3.7 (Type II of Hamilton-Jacobi Theorem for a Magnetic Hamiltonian System)** For the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\) with the magnetic symplectic form \(\omega^B = \omega - \pi^*_Q B\) on \(T^*Q\), where \(\omega\) is the canonical symplectic form on \(T^*Q\) and \(B\) is a closed two-form on \(Q\), assume that \(\gamma : Q \to T^*Q\) is an one-form on \(Q\), and \(\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q\), and for any symplectic map \(\varepsilon : T^*Q \to T^*Q\) with respect to \(\omega^B\), denote by \(X^\varepsilon = T\pi_Q \cdot X^B_H \cdot \varepsilon\), where \(X^B_H\) is the dynamical vector field of the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\), that is, the magnetic Hamiltonian vector field. Then \(\varepsilon\) is a solution of the equation \(T\varepsilon \cdot X^B_H \cdot \varepsilon = T\lambda \cdot X^B_H \cdot \varepsilon\), if and only if it is a solution of the equation \(T\gamma \cdot X^\varepsilon = X^B_H \cdot \varepsilon\), where \(X^B_H \in TT^*Q\) is the magnetic Hamiltonian vector field of the function \(H \cdot \varepsilon : T^*Q \to \mathbb{R}\). The equation \(T\gamma \cdot X^\varepsilon = X^B_H \cdot \varepsilon\), is called the Type II of Hamilton-Jacobi equation for the magnetic Hamiltonian system \((T^*Q, \omega^B, H)\).

**Proof:** If we take that \(v = X^B_H \cdot \varepsilon \in TT^*Q\), and for any \(w \in TT^*Q\), \(T\lambda(w) \neq 0\), from Lemma 3.4 we have that

\[
\begin{aligned}
\omega^B(T\gamma \cdot X^\varepsilon, w) &= \omega^B(T\gamma \cdot T\pi_Q \cdot X^B_H \cdot \varepsilon, w) = \omega^B(T\gamma \cdot \pi_Q \cdot X^B_H \cdot \varepsilon, w) \\
&= \omega^B(X^B_H \cdot \varepsilon, w - T(\gamma \cdot \pi_Q) \cdot w) - (d\gamma + B)(T\pi_Q(X^B_H \cdot \varepsilon), T\pi_Q(w)) \\
&= \omega^B(X^B_H \cdot \varepsilon, w) - \omega^B(X^B_H \cdot \varepsilon, T\lambda \cdot w) + \lambda \omega^B(X^B_H \cdot \varepsilon, w) \\
&= \omega^B(X^B_H \cdot \varepsilon, w) - \omega^B(X^B_H \cdot \varepsilon, T\lambda \cdot w) + \omega^B(T\lambda \cdot X^B_H \cdot \varepsilon, T\lambda \cdot w).
\end{aligned}
\]

Because \(\varepsilon : T^*Q \to T^*Q\) is symplectic with respect to \(\omega^B\), and hence \(X^B_H \cdot \varepsilon = T\varepsilon \cdot X^B_H \cdot \varepsilon\), along \(\varepsilon\). From the above arguments, we can obtain that

\[
\begin{aligned}
\omega^B(T\gamma \cdot X^\varepsilon, w) - \omega^B(X^B_H \cdot \varepsilon, w) &= -\omega^B(X^B_H \cdot \varepsilon, T\lambda \cdot w) + \omega^B(T\lambda \cdot X^B_H \cdot \varepsilon, T\lambda \cdot w) \\
&= -\omega^B(T\varepsilon \cdot X^B_H \cdot \varepsilon, T\lambda \cdot w) + \omega^B(T\lambda \cdot X^B_H \cdot \varepsilon, T\lambda \cdot w) \\
&= \omega^B(T\lambda \cdot X^B_H \cdot \varepsilon - T\varepsilon \cdot X^B_H \cdot \varepsilon, T\lambda \cdot w).
\end{aligned}
\]

Because the magnetic symplectic form \(\omega^B\) is non-degenerate, it follows that \(T\gamma \cdot X^\varepsilon = X^B_H \cdot \varepsilon\), is equivalent to \(T\varepsilon \cdot X^B_H \cdot \varepsilon = T\lambda \cdot X^B_H \cdot \varepsilon\). Thus, \(\varepsilon\) is a solution of the equation \(T\varepsilon \cdot X^B_H \cdot \varepsilon = T\lambda \cdot X^B_H \cdot \varepsilon\), if and only if it is a solution of the Type II of Hamilton-Jacobi equation \(T\gamma \cdot X^\varepsilon = X^B_H \cdot \varepsilon\). ■
Remark 3.8 It is worthy of noting that, the Type I of Hamilton-Jacobi equation $T \gamma \cdot X^\gamma = X^B_H \cdot \gamma$, is the equation of the differential one-form $\gamma$; and the Type II of Hamilton-Jacobi equation $T \gamma \cdot X^\varepsilon = X^B_H \cdot \varepsilon$, is the equation of the symplectic diffeomorphism map $\varepsilon$. When $B = 0$, in this case the magnetic symplectic form $\omega^B$ is just the canonical symplectic form $\omega$ on $T^*Q$, and the magnetic Hamiltonian system is just the canonical Hamiltonian system itself. From the above Type I and Type II of Hamilton-Jacobi theorems, that is, Theorem 3.5 and Theorem 3.7, we can get the Theorem 2.5 and Theorem 2.6 in Wang [28]. It shows that Theorem 3.5 and Theorem 3.7 can be regarded as an extension of two types of Hamilton-Jacobi theorem for Hamiltonian system given in [28] to that for the magnetic Hamiltonian system.

4 Hamilton-Jacobi Equation for Distributional Magnetic Hamiltonian System

In this section we shall derive precisely the geometric constraint conditions of the induced distributional two-form for the nonholonomic dynamical vector field of distributional magnetic Hamiltonian system, that is, the two types of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system. In order to do this, in the following we first give some important notions and prove a key lemma, which is an important tool for the proofs of two types of Hamilton-Jacobi theorem for the distributional magnetic Hamiltonian system.

Assume that $D \subset TQ$ is a $D$-regularly nonholonomic constraint, and the constraint submanifold $\mathcal{M} = FL(D) \subset T^*Q$, the distribution $F = (T\pi_Q)^{-1}(D) \subset TT^*Q$, and $\gamma : Q \to T^*Q$ is an one-form on $Q$, and $B$ is a closed two-form on $Q$, in the following we first introduce two weaker notions.

Definition 4.1 (i) The one-form $\gamma$ is called to be closed on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, if for any $v, w \in TT^*Q$, and $T\pi_Q(v), T\pi_Q(w) \in D$, we have that $d\gamma(T\pi_Q(v), T\pi_Q(w)) = 0$;

(ii) The one-form $\gamma : Q \to T^*Q$ is called that satisfies condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, if for any $v, w \in TT^*Q$, and $T\pi_Q(v), T\pi_Q(w) \in D$, we have that $(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0$.

From the above Definition 4.1, we know that, when $B = 0$, the notion that, $\gamma$ satisfies condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, become the notion that $\gamma$ is closed on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$. On the other hand, it is worthy of noting that the notion that $\gamma$ satisfies condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, is weaker than the notion that $\gamma$ satisfies condition $d\gamma = -B$ on $D$, that is, $(d\gamma + B)(x, y) = 0, \forall x, y \in D$. In fact, if $\gamma$ satisfies condition $d\gamma = -B$ on $D$, then it must satisfy condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$. Conversely, if $\gamma$ satisfies condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, then it may not satisfy condition $d\gamma = -B$ on $D$. We can prove a general result as follows, which states that the notion that, the $\gamma$ satisfies condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, is not equivalent to the notion that $\gamma$ satisfies condition $d\gamma = -B$ on $D$.

Proposition 4.2 Assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$ and it doesn’t satisfy condition $d\gamma = -B$ on $D$. We define the set $N$, which is a subset of $TQ$, such that the one-form $\gamma$ on $N$ satisfies the condition that for any $x, y \in N$, $(d\gamma + B)(x, y) \neq 0$. Denote $\text{Ker}(T\pi_Q) = \{ u \in TT^*Q | T\pi_Q(u) = 0 \}$, and $T\gamma : TQ \to TT^*Q$. If $T\gamma(N) \subset \text{Ker}(T\pi_Q)$, then $\gamma$ satisfies condition $d\gamma = -B$ with respect to $T\pi_Q : TT^*Q \to TQ$, and hence $\gamma$ satisfies condition $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$.
Proof: If the \( \gamma : Q \to T^*Q \) doesn’t satisfy condition \( d\gamma = -B \) on \( D \), then it doesn’t yet satisfy condition \( d\gamma = -B \). From the proof of Lemma 3.3, for any \( v, w \in TT^*Q \), we have always that
\[(d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0. \]
In particular, for any \( v, w \in TT^*Q \), and \( T\pi_Q(v), T\pi_Q(w) \in D \), we have \((d\gamma + B)(T\pi_Q(v), T\pi_Q(w)) = 0. \) that is, \( \gamma \) satisfies condition that \( d\gamma = -B \) on \( D \) with respect to \( T\pi_Q : TT^*Q \to TQ \).

Now, we prove the following Lemma 4.3. It is worthy of noting that this lemma and Lemma 3.4 given in §3 are the important tool for the proofs of the two types of Hamilton-Jacobi theorems for the distributional magnetic Hamiltonian system and the nonholonomic reduced distributional magnetic Hamiltonian system.

**Lemma 4.3** Assume that \( \gamma : Q \to T^*Q \) is an one-form on \( Q \), and \( \lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q \), and \( \omega \) is the canonical symplectic form on \( T^*Q \), and \( \omega^B = \omega - \pi_Q^*B \) is the magnetic symplectic form on \( T^*Q \). If the Lagrangian \( L \) is \( D \)-regular, and \( \text{Im}(\gamma) \subset \mathcal{M} = FL(D) \), then we have that \( X^B_H \cdot \gamma \in \mathcal{F} \) along \( \gamma \), and \( X^B_H \cdot \lambda \in \mathcal{F} \) along \( \lambda \), that is, \( T\pi_Q(X^B_H \cdot \gamma(q)) \in \mathcal{D}_q, \forall q \in Q \), and \( T\pi_Q(X^B_H \cdot \lambda(q, p)) \in \mathcal{D}_q, \forall q \in Q, (q, p) \in T^*Q \). Moreover, if a symplectic map \( \varepsilon : T^*Q \to T^*Q \) with respect to the magnetic symplectic form \( \omega^B \) satisfies the condition \( \varepsilon(\mathcal{M}) \subset \mathcal{M} \), then we have that \( X^B_H \cdot \varepsilon \in \mathcal{F} \) along \( \varepsilon \).

**Proof:** Under the canonical cotangent bundle coordinates, for any \( q \in Q, (q, p) \in T^*Q \), we have that
\[
X^B_H \cdot \gamma(q) = \left( \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} - \frac{\partial H}{\partial q^i} \frac{\partial}{\partial p_i} \right) - \sum_{i=1}^{n} B_{ij} \frac{\partial}{\partial p_j} \frac{\partial}{\partial p_i} \right) \gamma(q).
\]
and
\[
X^B_H \cdot \lambda(q, p) = \left( \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} - \frac{\partial H}{\partial q^i} \frac{\partial}{\partial p_i} \right) - \sum_{i=1}^{n} B_{ij} \frac{\partial}{\partial p_j} \frac{\partial}{\partial p_i} \right) \gamma(q) \cdot \pi_Q(q, p).
\]

Then,
\[
T\pi_Q(X^B_H \cdot \gamma(q)) = T\pi_Q(X^B_H \cdot \lambda(q, p)) = \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} \right) \gamma(q) \in T_q Q.
\]
Since \( \text{Im}(\gamma) \subset \mathcal{M} \), and \( \gamma(q) \in \mathcal{M}(q, p) = FL(D_q) \), from the Lagrangian \( L \) is \( D \)-regular, and \( FL \) is a diffeomorphism, then there exists a point \( (q, v_q) \in D_q \), such that \( FL(q, v_q) = \gamma(q) \). Thus,
\[
T\pi_Q(X^B_H \cdot \gamma(q)) = T\pi_Q(X^B_H \cdot \lambda(q, p)) = FL(q, v_q) \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} \right) \in D_q,
\]

it follows that \( X^B_H \cdot \gamma \in \mathcal{F} \) along \( \gamma \), and \( X^B_H \cdot \lambda \in \mathcal{F} \) along \( \lambda \). Moreover, for the symplectic map \( \varepsilon : T^*Q \to T^*Q \) with respect to the magnetic symplectic form \( \omega^B \), we have that
\[
X^B_H \cdot \varepsilon(q, p) = \left( \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} - \frac{\partial H}{\partial q^i} \frac{\partial}{\partial p_i} \right) - \sum_{i=1}^{n} B_{ij} \frac{\partial}{\partial p_j} \frac{\partial}{\partial p_i} \right) \varepsilon(q, p).
\]
If \( \varepsilon \) satisfies the condition \( \varepsilon(\mathcal{M}) \subset \mathcal{M} \), then for any \( (q, p) \in \mathcal{M}(q, p) \), we have that \( \varepsilon(q, p) \in \mathcal{M}(q, p) \), and there exists a point \( (q, v_q) \in D_q \), such that \( FL(q, v_q) = \varepsilon(q, p) \). Thus,
\[
T\pi_Q(X^B_H \cdot \varepsilon(q, p)) = \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} \right) \varepsilon(q, p) = FL(q, v_q) \sum_{i=1}^{n} \left( \frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} \right) \in D_q,
\]

it follows that \( X^B_H \cdot \varepsilon \in \mathcal{F} \) along \( \varepsilon \). ■
We note that for a nonholonomic magnetic Hamiltonian system, under the restriction given by nonholonomic constraint, in general, the dynamical vector field of a nonholonomic magnetic Hamiltonian system may not be Hamiltonian. On the other hand, since the distributional magnetic Hamiltonian system is determined by a non-degenerate distributional two-form induced from the magnetic symplectic form, but, the non-degenerate distributional two-form is not a "true two-form" on a manifold, and hence the leading distributional magnetic Hamiltonian system can not be Hamiltonian. Thus, we can not describe the Hamilton-Jacobi equations for the nonholonomic distributional magnetic Hamiltonian system from the viewpoint of generating function as in the classical Hamiltonian case, that is, we cannot prove the Hamilton-Jacobi theorem for the nonholonomic magnetic Hamiltonian system, just like same as the above Theorem 1.1. Since the distributional magnetic Hamiltonian system is a dynamical system closely related to a magnetic Hamiltonian system, in the following by using Lemma 3.4, Lemma 4.3, and the non-degenerate distributional two-form $\omega_B^K$, we can derive precisely the geometric constraint conditions of the non-degenerate and the nonholonomic dynamical vector field $X^K_B$, that is, the two types of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system $(K, \omega^K_B, H_K)$. At first, we prove the following Type I of Hamilton-Jacobi theorem for the distributional magnetic Hamiltonian system.

**Theorem 4.4 (Type I of Hamilton-Jacobi Theorem for the Distributional Magnetic Hamiltonian System)** For the nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, \mathcal{D}, H)$ with an associated distributional magnetic Hamiltonian system $(K, \omega^K_B, H_K)$, assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$, and $X^\gamma = T\pi_Q \cdot X^B_H \cdot \gamma$, where $X^B_H$ is the magnetic Hamiltonian vector field of the associated unconstrained magnetic Hamiltonian system $(T^*Q, \omega^B, H)$. Moreover, assume that $\text{Im}(\gamma) \subset \mathcal{M} = \mathcal{F}(\mathcal{D})$, and $\text{Im}(T\gamma) \subset K$. If the one-form $\gamma : Q \to T^*Q$ satisfies the condition, $d\gamma = -B$ on $\mathcal{D}$ with respect to $T\pi_Q : T^*Q \to TQ$, then $\gamma$ is a solution of the equation $T\gamma \cdot X^\gamma = X^K_B \cdot \gamma$. Here $X^K_B$ is the nonholonomic dynamical vector field of the distributional magnetic Hamiltonian system $(K, \omega^K_B, H_K)$. The equation $T\gamma \cdot X^\gamma = X^K_B \cdot \gamma$ is called the Type I of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system $(K, \omega^K_B, H_K)$. Here the maps involved in the theorem are shown in the following Diagram-3.

![Diagram-3](image)

**Proof:** At first, we note that $\text{Im}(\gamma) \subset \mathcal{M}$, and $\text{Im}(T\gamma) \subset K$, in this case, $\omega^K_B \cdot \tau_K = \tau_K \cdot \omega^K_M = \tau_K \cdot i^M_M \cdot \omega , \text{along } \text{Im}(T\gamma)$. Moreover, from the distributional magnetic Hamiltonian equation (2.2), we have that $X^K_B = \tau_K \cdot X^B_H$, and $\tau_K \cdot X^B_H \cdot \gamma = X^K_B \cdot \gamma$. Thus, using the non-degenerate distributional two-form $\omega^K_B$, from Lemma 3.4(ii) and Lemma 4.3, if we take that $v = X^B_H \cdot \gamma \in \mathcal{F}$, and for any
\( w \in \mathcal{F}, \ T\lambda(w) \neq 0, \) and \( \tau_{\mathcal{K}} \cdot w \neq 0, \) then we have that

\[
\omega_{\mathcal{K}}^B(T\gamma \cdot X^\gamma, \ \tau_{\mathcal{K}} \cdot w) = \omega_{\mathcal{K}}^B(\tau_{\mathcal{K}} \cdot T\gamma \cdot X^\gamma, \ \tau_{\mathcal{K}} \cdot w)
\]

\[
= \tau_{\mathcal{K}} \cdot i_{\mathcal{M}}^* \cdot \omega^B(T\gamma \cdot T\pi_Q \cdot X_{\mathcal{H}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot w)
\]

\[
= \tau_{\mathcal{K}} \cdot i_{\mathcal{M}}^* \cdot \omega^B(T\gamma \cdot T\pi_Q \cdot X_{\mathcal{H}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot w) - \tau_{\mathcal{K}} \cdot i_{\mathcal{M}} \cdot \omega^B(X_{\mathcal{H}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot w)
\]

where we have used that \( \tau_{\mathcal{K}} \cdot T\gamma = T\gamma, \) since \( \text{Im}(T\gamma) \subseteq \mathcal{K}, \) and \( \tau_{\mathcal{K}} \cdot X_{\mathcal{H}}^B \cdot \gamma = X_{\mathcal{K}}^B \cdot \gamma \in \mathcal{K}. \) Note that \( X_{\mathcal{H}}^B \cdot \gamma, \ \gamma, \ w \in \mathcal{F}, \) and \( T\pi_Q(X_{\mathcal{K}}^B), \ \pi_Q(w) \in \mathcal{D}. \) If the one-form \( \gamma : Q \to T^*Q \) satisfies the condition, \( d\gamma = -B \) on \( \mathcal{D} \) with respect to \( T\pi_Q : TT^*Q \to TQ, \) then \( (d\gamma + B)(T\pi_Q \cdot X_{\mathcal{H}}^B \cdot \gamma, \ T\pi_Q \cdot w) = 0, \) and hence

\[
\tau_{\mathcal{K}} \cdot i_{\mathcal{M}} \cdot (d\gamma + B)(T\pi_Q(X_{\mathcal{H}}^B \cdot \gamma), \ T\pi_Q(w)) = 0,
\]

Thus, we have that

\[
\omega_{\mathcal{K}}^B(T\gamma \cdot X^\gamma, \ \tau_{\mathcal{K}} \cdot w) - \omega_{\mathcal{K}}^B(X_{\mathcal{K}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot w) = -\omega_{\mathcal{K}}^B(X_{\mathcal{K}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot T\gamma \cdot T\pi_Q(w)). \tag{4.1}
\]

If \( \gamma \) satisfies the equation \( T\gamma \cdot X^\gamma = X_{\mathcal{K}}^B \cdot \gamma, \) from Lemma 3.4(i) we know that the right side of (4.1) becomes that

\[
-\omega_{\mathcal{K}}^B(X_{\mathcal{K}}^B \cdot \gamma, \ \tau_{\mathcal{K}} \cdot T\gamma \cdot T\pi_Q(w)) = -\omega_{\mathcal{K}}^B(T\gamma \cdot X^\gamma, \ \tau_{\mathcal{K}} \cdot T\gamma \cdot T\pi_Q(w))
\]

\[
= -\omega_{\mathcal{K}}^B(\tau_{\mathcal{K}} \cdot T\gamma \cdot X^\gamma, \ \tau_{\mathcal{K}} \cdot T\gamma \cdot T\pi_Q(w))
\]

\[
= -\tau_{\mathcal{K}} \cdot i_{\mathcal{M}} \cdot \omega^B(T\gamma \cdot T\pi_Q(X_{\mathcal{H}}^B \cdot \gamma), \ T\gamma \cdot T\pi_Q(w))
\]

\[
= -\tau_{\mathcal{K}} \cdot i_{\mathcal{M}} \cdot \omega^B(X_{\mathcal{H}}^B \cdot \gamma, \ w)
\]

Because the distributional two-form \( \omega_{\mathcal{K}}^B \) is non-degenerate, the left side of (4.1) equals zero, only when \( \gamma \) satisfies the equation \( T\gamma \cdot X^\gamma = X_{\mathcal{K}}^B \cdot \gamma. \) Thus, if the one-form \( \gamma : Q \to T^*Q \) satisfies the condition that \( d\gamma = -B \) on \( \mathcal{D} \) with respect to \( T\pi_Q : TT^*Q \to TQ, \) then \( \gamma \) must be a solution of the Type I of Hamilton-Jacobi equation \( T\gamma \cdot X^\gamma = X_{\mathcal{K}}^B \cdot \gamma, \) for the distributional magnetic Hamiltonian system \((\mathcal{K}, \omega_{\mathcal{K}}^B, H_{\mathcal{K}}). \)

It is worthy of noting that, when \( B = 0, \) in this case the magnetic symplectic form \( \omega^B \) is just the canonical symplectic form \( \omega \) on \( T^*Q, \) and the nonholonomic magnetic Hamiltonian system \((T^*Q, \omega^B, \mathcal{D}, H)\) becomes the nonholonomic Hamiltonian system \((T^*Q, \omega, \mathcal{D}, H)\) with the canonical symplectic form \( \omega, \) and the distributional magnetic Hamiltonian system \((\mathcal{K}, \omega_{\mathcal{K}}^B, H_{\mathcal{K}})\) becomes the distributional Hamiltonian system \((\mathcal{K}, \omega_{\mathcal{K}}, H_{\mathcal{K}}), \) and the condition that the one-form \( \gamma : Q \to T^*Q \) satisfies the condition that \( d\gamma = -B \) on \( \mathcal{D} \) with respect to \( T\pi_Q : TT^*Q \to TQ, \) becomes that \( \gamma \) is closed on \( \mathcal{D} \) with respect to \( T\pi_Q : TT^*Q \to TQ. \) Thus, from above Theorem 4.4, we can obtain Theorem 3.5 in León and Wang [14], that is, the Type I of Hamilton-Jacobi theorem for the distributional Hamiltonian system. On the other hand, from the proofs of Theorem 3.5 in León and Wang [14], we know that, if the one-form \( \gamma : Q \to T^*Q \) is not closed on \( \mathcal{D} \) with respect to \( T\pi_Q : TT^*Q \to TQ, \) then the \( \gamma \) is not yet closed on \( \mathcal{D}, \) that is, \( d\gamma(x, y) \neq 0, \ \forall \ x, y \in \mathcal{D}, \) and hence \( \gamma \) is not
yet closed on $Q$. However, in this case, we note that $d \cdot d \gamma = d^2 \gamma = 0$, and hence the $d \gamma$ is a closed two-form on $Q$. Thus, we can construct a magnetic symplectic form on $T^*Q$, $\omega^B = \omega + \pi_Q^*(d\gamma)$, where $B = -d\gamma$. Moreover, we can also construct a nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, D, H)$ with an associated distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$, which satisfies the distributional magnetic Hamiltonian equation (2.2), $i_{X^B_K} \omega^B_K = dH_K$. In this case, the one-form $\gamma : Q \to T^*Q$ satisfies also the condition that $d\gamma = -B$ on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$, by using Lemma 3.4, Lemma 4.3, and the magnetic Hamiltonian vector field $X^B_H$, from Theorem 4.4 we can obtain the following Theorem 4.5.

**Theorem 4.5** For a given nonholonomic magnetic Hamiltonian system $(T^*Q, \omega, D, H)$ with the canonical symplectic form $\omega$ on $T^*Q$ and $D$-completely and $D$-regularly nonholonomic constraint $D \subset TQ$, and assume that the one-form $\gamma : Q \to T^*Q$ is not closed on $D$ with respect to $T\pi_Q : TT^*Q \to TQ$. Then one can construct a magnetic symplectic form on $T^*Q$, $\omega^B = \omega + \pi_Q^*(d\gamma)$, where $B = -d\gamma$, and a nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, D, H)$ with an associated distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$. Denote $X^B = T\pi_Q \cdot X^B_H \cdot \gamma$, where $X^B_H$ is the dynamical vector field of the magnetic Hamiltonian system $(T^*Q, \omega^B, H)$. Then $\gamma$ is a solution of the Type I of Hamilton-Jacobi equation $T \gamma \cdot X^B = X^B_K \cdot \gamma$, for the distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$.

Next, for any symplectic map $\varepsilon : T^*Q \to T^*Q$ with respect to the magnetic symplectic form $\omega^B$, we can prove the following Type II of Hamilton-Jacobi theorem for the distributional magnetic Hamiltonian system. For convenience, the maps involved in the following theorem and its proof are shown in Diagram-4.

![Diagram-4](image)

**Theorem 4.6** (Type II of Hamilton-Jacobi Theorem for a Distributional Magnetic Hamiltonian System) For the nonholonomic magnetic Hamiltonian system $(T^*Q, \omega^B, D, H)$ with an associated distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$, assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$, and $\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q$, and for any symplectic map $\varepsilon : T^*Q \to T^*Q$ with respect to the magnetic symplectic form $\omega^B$, denote by $X^\varepsilon = T\pi_Q \cdot X^B_H \cdot \varepsilon$, where $X^B_H$ is the dynamical vector field of the magnetic Hamiltonian system $(T^*Q, \omega^B, H)$. Moreover, assume that $\text{Im}(\gamma) \subset M = FL(D)$, and $\varepsilon(M) \subset M$, and $\text{Im}(T\gamma) \subset K$. Then $\varepsilon$ is a solution of the equation $T\gamma \cdot X^\varepsilon = X^B_K \cdot \varepsilon$, if and only if it is a solution of the equation $T\gamma \cdot X^\varepsilon = T\lambda \cdot X^B_H \cdot \varepsilon$, if and only if it is a solution of the equation $T\gamma \cdot X^\varepsilon = X^B_K \cdot \varepsilon$. Here $X^B_H \cdot \varepsilon$ is the magnetic Hamiltonian vector field of the function $H \cdot \varepsilon : T^*Q \to \mathbb{R}$, and $X^B_K$ is the dynamical vector field of the distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$. The equation $T\gamma \cdot X^\varepsilon = X^B_K \cdot \varepsilon$, is called the Type II of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system $(K, \omega^B_K, H_K)$.

**Proof:** In the same way, we note that $\text{Im}(\gamma) \subset M$, and $\text{Im}(T\gamma) \subset K$, in this case, $\omega^B_K \cdot \tau_K = \tau_K \cdot \omega^B_M = \tau_K \cdot i_M^* \omega^B$, along $\text{Im}(T\gamma)$. Moreover, from the distributional magnetic Hamiltonian equation (2.2), we have that $X^B_K = \tau_K \cdot X^B_H$, and $\tau_K \cdot X^B_H \cdot \varepsilon = X^B_K \cdot \varepsilon$. Note that $\text{Im}(M) \subset M$, and $T\pi_Q(X^B_K \cdot \varepsilon(q,p)) \in D_q$, $\forall q \in Q$, $(q,p) \in M \subset \mathbb{R}$. Thus, using the non-degenerate distributional two-form $\omega^B_K$ from Lemma 3.4 and Lemma 4.3, if we take that
\[ v = X_H^B \cdot \varepsilon \in \mathcal{F}, \] and for any \( w \in \mathcal{F}, \) \( T\lambda(w) \neq 0, \) and \( \tau_K \cdot w \neq 0, \) then we have that
\[
\omega_K^B(T \gamma \cdot X^\varepsilon, \tau_K \cdot w) = \omega_K^B(\tau_K \cdot T \gamma \cdot X^\varepsilon, \tau_K \cdot w)
\]
\[
= \tau_K \cdot i_M^* \cdot \omega^B(T \gamma \cdot T \pi_Q \cdot X_H^B \cdot \varepsilon, w) = \tau_K \cdot i_M^* \cdot \omega^B(T \gamma \cdot \pi_Q \cdot X_H^B \cdot \varepsilon, w)
\]
\[
= \tau_K \cdot i_M^* \cdot (\omega^B(X_H^B \cdot \varepsilon, w - T(\gamma \cdot \pi_Q) \cdot w) - (d\gamma + B)(T \pi_Q(X_H^B \cdot \varepsilon), T \pi_Q(w)))
\]
\[
= \tau_K \cdot i_M^* \cdot \omega^B(X_H^B \cdot \varepsilon, w) - \tau_K \cdot i_M^* \cdot \omega^B(X_H^B \cdot \varepsilon, T \lambda \cdot w)
\]
\[
- \tau_K \cdot i_M^* \cdot (d\gamma + B)(T \pi_Q(X_H^B \cdot \varepsilon), T \pi_Q(w))
\]
\[
= \omega_K^B(\tau_K \cdot X_H^B \cdot \varepsilon, \tau_K \cdot w) - \omega_K^B(\tau_K \cdot X_H^B \cdot \varepsilon, \tau_K \cdot T \lambda \cdot w)
\]
\[
+ \tau_K \cdot i_M^* \cdot \lambda^* \omega^B(X_H^B \cdot \varepsilon, w)
\]
\[
= \omega_K^B(X_K^B \cdot \varepsilon, \tau_K \cdot w) - \omega_K^B(\tau_K \cdot X_H^B \cdot \varepsilon, T \lambda \cdot w) + \omega_K^B(T \lambda \cdot X_H^B \cdot \varepsilon, T \lambda \cdot w),
\]
where we have used that \( \tau_K \cdot T \gamma = T \gamma, \tau_K \cdot T \lambda = T \lambda, \) and \( \tau_K \cdot X_H^B \cdot \varepsilon = X_K^B \cdot \varepsilon, \) since \( \text{Im}(T \gamma) \subset K. \)

Note that \( \varepsilon : T^*Q \rightarrow T^*Q \) is symplectic with respect to the magnetic symplectic form \( \omega^B, \) and \( X_H^B \cdot \varepsilon = T\varepsilon \cdot X_H^B, \) along \( \varepsilon, \) and hence \( \tau_K \cdot X_H^B \cdot \varepsilon = \tau_K \cdot T\varepsilon \cdot X_H^B, \) along \( \varepsilon. \) Then we have that
\[
\omega_K^B(T \gamma \cdot X^\varepsilon, \tau_K \cdot w) - \omega_K^B(X_K^B \cdot \varepsilon, \tau_K \cdot w)
\]
\[
= -\omega_K^B(\tau_K \cdot X_H^B \cdot \varepsilon, T \lambda \cdot w) + \omega_K^B(T \lambda \cdot X_H^B \cdot \varepsilon, T \lambda \cdot w)
\]
\[
= \omega_K^B(T \lambda \cdot X_H^B \cdot \varepsilon - \tau_K \cdot T\varepsilon \cdot X_H^B, T \lambda \cdot w).
\]

Because the induced distributional two-form \( \omega_K^B \) is non-degenerate, it follows that the equation \( T \gamma \cdot X^\varepsilon = X_K^B \cdot \varepsilon, \) is equivalent to the equation \( \tau_K \cdot T\varepsilon \cdot X_H^B = T \lambda \cdot X_H^B \cdot \varepsilon. \) Thus, \( \varepsilon \) is a solution of the equation \( \tau_K \cdot T\varepsilon \cdot X_H^B = T \lambda \cdot X_H^B \cdot \varepsilon, \) if and only if it is a solution of the Type II of Hamilton-Jacobi equation \( T \gamma \cdot X^\varepsilon = X_K^B \cdot \varepsilon. \]

**Remark 4.7** It is worthy of noting that, the Type I of Hamilton-Jacobi equation \( T \gamma \cdot X^\varepsilon = X_K^B \cdot \gamma, \) is the equation of the differential one-form \( \gamma; \) and the Type II of Hamilton-Jacobi equation \( T \gamma \cdot X^\varepsilon = X_K^B \cdot \varepsilon, \) is the equation of the symplectic diffeomorphism map \( \varepsilon. \) If the nonholonomic magnetic Hamiltonian system we considered has not any constrains, in this case, the distributional magnetic Hamiltonian system is just the magnetic Hamiltonian system itself. From the above Type I and Type II of Hamilton-Jacobi theorems, that is, Theorem 4.4 and Theorem 4.6, we can get the Theorem 3.5 and Theorem 3.7. It shows that Theorem 4.4 and Theorem 4.6 can be regarded as an extension of two types of Hamilton-Jacobi theorem for the magnetic Hamiltonian system to the system with nonholonomic context. On the other hand, when \( B = 0, \) in this case the magnetic symplectic form \( \omega^B \) is just the canonical symplectic form \( \omega \) on \( T^*Q, \) and the distributional magnetic Hamiltonian system is just the distributional Hamiltonian system itself. From the above Type I and Type II of Hamilton-Jacobi theorems, that is, Theorem 4.4 and Theorem 4.6, we can get the Theorem 3.5 and Theorem 3.6 given by León and Wang in [14]. It shows that Theorem 4.4 and Theorem 4.6 can be regarded as an extension of two types of Hamilton-Jacobi theorem for the distributional Hamiltonian system to that for the distributional magnetic Hamiltonian system.

## 5 Nonholonomic Reduced Distributional Magnetic Hamiltonian System

It is well-known that the reduction for the mechanical system with symmetry is an important subject and it is widely studied in the theory of mathematics and mechanics, as well as applications; see Abraham and Marsden [1], Arnold [2], Libermann and Marle [15], Marsden [16], Marsden et al. [17, 18], Marsden and Ratiu [19], Marsden and Weinstein [21], and Ortega and Ratiu [22] and so on, for more details and development. In particular, the reduction of nonholonomically
constrained mechanical systems is also very important subject in geometric mechanics, and it is regarded as a useful tool for simplifying and studying concrete nonholonomic systems, see Bates and Śniatycki [3], Cantrijn et al. [4], Cendra et al. [7], Cushman et al. [8] and [9], Koiller [11], León and Rodrigues [13] and León and Wang [14] and so on.

In this section, we shall consider the nonholonomic reduction and Hamilton-Jacobi theory of a nonholonomic magnetic Hamiltonian system with symmetry. At first, we give the definition of a nonholonomic magnetic Hamiltonian system with symmetry. Then, by using the similar method in León and Wang [14] and Bates and Śniatycki [3], and by analyzing carefully the dynamics and structure of the nonholonomic magnetic Hamiltonian system with symmetry, we give a geometric formulation of the nonholonomic reduced distributional magnetic Hamiltonian system. Moreover, we derive precisely the geometric constraint conditions of the non-degenerate, and nonholonomic reduced distributional two-form for the nonholonomic reducible dynamical vector field, that is, the two types of Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system, which are an extension of the above two types of Hamilton-Jacobi equation for the distributional magnetic Hamiltonian system given in section 4 under nonholonomic reduction.

Assume that the Lie group $G$ acts smoothly on the manifold $Q$ by the left, and we also consider the natural lifted actions on $TQ$ and $T^*Q$, and assume that the cotangent lifted action on $T^*Q$ is free, proper and symplectic with respect to the magnetic symplectic form $ω^B = ω − πQ^*_QB$ on $T^*Q$, where $ω$ is the canonical symplectic form on $T^*Q$ and $B$ is a closed two-form on $Q$. The orbit space $T^*Q/G$ is a smooth manifold and the canonical projection $πG : T^*Q → T^*Q/G$ is a surjective submersion. Assume that $H : T^*Q → ℝ$ is a $G$-invariant Hamiltonian, and the $D$-completely and $D$-regularly nonholonomic constraint $D ⊂ TQ$ is a $G$-invariant distribution, that is, the tangent of group action maps $D_q$ to $D_{ggq}$ for any $q ∈ Q$. A nonholonomic magnetic Hamiltonian system with symmetry is 5-tuple $(T^*Q, G, ω^B, D, H)$, which is a magnetic Hamiltonian system with symmetry and $G$-invariant nonholonomic constraint $D$.

In the following we first consider the nonholonomic reduction of a magnetic Hamiltonian system with symmetry $(T^*Q, G, ω^B, D, H)$. Note that the Legendre transformation $FL : TQ → T^*Q$ is a fiber-preserving map, and $D ⊂ TQ$ is $G$-invariant for the tangent lifted left action $ΦT : G × TQ → TQ$, then the constraint submanifold $M = FL(D) ⊂ T^*Q$ is $G$-invariant for the cotangent lifted left action $Φ^*: G × T^*Q → T^*Q$. For the nonholonomic magnetic Hamiltonian system with symmetry $(T^*Q, G, ω^B, D, H)$, in the same way, we define the distribution $F$, which is the pre-image of the nonholonomic constraints $D$ for the map $TπQ : TT^*Q → TQ$, that is, $F = (TπQ)^{-1}(D)$, and the distribution $K = F ∩ TM$. Moreover, we can also define the distributional magnetic two-form $ω^K_B$, which is induced from the magnetic symplectic form $ω^B$ on $T^*Q$, that is, $ω^K_B = τK · ω^K_M$, and $ω^K_M = i^K_Mω^B$. If the admissibility condition $dimM = rankF$ and the compatibility condition $TM ∩ F^⊥ = \{0\}$ hold, then $ω^K_B$ is non-degenerate as a bilinear form on each fibre of $K$, there exists a vector field $X^K_B$ on $M$ which takes values in the constraint distribution $K$, such that for the function $H_K$, the following distributional magnetic Hamiltonian equation holds, that is,

$$i_{X^K_B}ω^K_B = dH_K,$$

where the function $H_K$ satisfies $dH_K = τK · dH_M$, and $H_M = τM · H$ is the restriction of $H$ to $M$, and from the equation (5.1), we have that $X^K_B = τK · X^K_H$.

In the following we define that the quotient space $\tilde{M} = M/G$ of the $G$-orbit in $M$ is a smooth manifold with projection $π/G : M → M(\subset T^*Q/G)$, which is a surjective submersion. The reduced magnetic symplectic form $ω^B_M = π^*_G · ω^B_M$ on $M$ is induced from the magnetic symplectic
form $\omega^B_M = \iota^*_M \omega^B$ on $M$. Since $G$ is the symmetry group of the system $(T^*Q, G, \omega^B, \mathcal{D}, H)$, all intrinsically defined vector fields and distributions are pushed down to $\bar{M}$. In particular, the vector field $X^B_M$ on $M$ is pushed down to a vector field $X^B_{\bar{M}} = T_{\pi/G} \cdot X^B_M$, and the distribution $\mathcal{K}$ is pushed down to a distribution $T_{\pi/G} \cdot \mathcal{K}$ on $\bar{M}$, and the Hamiltonian $\bar{H}$ is pushed down to $h_{\bar{M}}$, such that $h_{\bar{M}} \cdot \pi/G = \tau_{\bar{M}} \cdot H$. However, $\omega^B_{\bar{K}}$ need not to be pushed down to a distributional two-form defined on $T_{\pi/G} \cdot \mathcal{K}$, despite of the fact that $\omega^B_{\bar{K}}$ is $G$-invariant. This is because there may be infinitesimal symmetry $\eta_K$ that lies in $M$, such that $\iota_{\eta_K} \omega^B_{\bar{K}} \neq 0$. From Bates and Šniatycki [3], we know that in order to eliminate this difficulty, $\omega^B_{\bar{K}}$ is restricted to a sub-distribution $\mathcal{U}$ of $\mathcal{K}$ defined by

$$\mathcal{U} = \{ \mathcal{v} \in \mathcal{K} \mid \omega^B_{\bar{K}}(\mathcal{u}, \mathcal{v}) = 0, \forall \mathcal{v} \in \mathcal{V} \cap \mathcal{K} \},$$

where $\mathcal{V}$ is the distribution on $M$ tangent to the orbits of $G$ in $M$ and it is spanned by the infinitesimal symmetries. Clearly, $\mathcal{U}$ and $\mathcal{V}$ are both $G$-invariant, project down to $\bar{M}$ and $T_{\pi/G} \cdot \mathcal{V} = 0$, and define the distribution $\bar{\mathcal{K}}$ by $\bar{\mathcal{K}} = T_{\pi/G} \cdot \mathcal{U}$. Moreover, we take that $\omega^B_U = \tau_{\mathcal{U}} \cdot \omega^B_M$ is the restriction of the induced magnetic symplectic form $\omega^B_M$ on $T^*M$ fibrewise to the distribution $\mathcal{U}$, where $\tau_{\mathcal{U}}$ is the restriction map to distribution $\mathcal{U}$, and the $\omega^B_U$ is pushed down to a distributional magnetic two-form $\omega^B_{\bar{K}}$ on $\bar{\mathcal{K}}$, such that $\pi_{\bar{\mathcal{K}}}^* \omega^B_{\bar{K}} = \omega^B_{\bar{K}}$. It is worthy of noting that the distributional magnetic two-form $\omega^B_{\bar{K}}$ is not a true two-form on a manifold, so it does not make sense to speak about it being closed. Thus, it is called the nonholonomic reduced distributional magnetic two-form to avoid any confusion.

From the above construction we know that, if the admissibility condition $\dim \bar{M} = \text{rank} \bar{F}$ and the compatibility condition $T_{\mathcal{M}} \cap \bar{\mathcal{F}} = \{0\}$ hold, where $\bar{\mathcal{F}}$ denotes the symplectic orthogonal of $\bar{F}$ with respect to the reduced magnetic symplectic form $\omega^B_M$, then the nonholonomic reduced distributional magnetic two-form $\omega^B_{\bar{K}}$ is non-degenerate as a bilinear form on each fibre of $\bar{K}$, and hence there exists a vector field $X^B_{\bar{K}}$ on $\bar{M}$ which takes values in the constraint distribution $\bar{\mathcal{K}}$, such that the nonholonomic reduced distributional magnetic Hamiltonian equation holds, that is,

$$\iota_{X^B_{\bar{K}}} \omega^B_{\bar{K}} = \text{d} h_{\bar{K}}, \tag{5.2}$$

where $\text{d} h_{\bar{K}}$ is the restriction of $\text{d} h_{\bar{M}}$ to $\bar{\mathcal{K}}$ and the function $h_{\bar{K}}$ satisfies $\text{d} h_{\bar{K}} = \tau_{\bar{K}} \cdot X^B_{\bar{K}}$, and $h_{\bar{\mathcal{M}}} \cdot \pi/G = H_{\bar{\mathcal{M}}}$ and $H_{\bar{\mathcal{M}}}$ is the restriction of the Hamiltonian function $H$ to $\bar{\mathcal{M}}$. In addition, from the distributional magnetic Hamiltonian equation (2.2), $\iota_{X^B_{\bar{K}}} \omega^B_{\bar{K}} = \text{d} H_{\bar{K}}$, we have that $X^B_{\bar{K}} = \tau_{\bar{K}} \cdot X^B_{\bar{K}}$, and from the nonholonomic reduced distributional magnetic Hamiltonian equation (5.2), $\iota_{X^B_{\bar{K}}} \omega^B_{\bar{K}} = \text{d} h_{\bar{K}}$, we have that $X^B_{\bar{K}} = \tau_{\bar{K}} \cdot X^B_{\bar{K}}$, where $X^B_{\bar{K}}$ is the magnetic Hamiltonian vector field of the function $h_{\bar{K}}$ with respect to the reduced magnetic symplectic form $\omega^B_{\bar{K}}$, and the vector fields $X^B_{\bar{K}}$ and $X^B_{\bar{K}}$ are $\pi/G$-related, that is, $X^B_{\bar{K}} \cdot \pi/G = T_{\pi/G} \cdot X^B_{\bar{K}}$. Thus, the geometrical formulation of a nonholonomic reduced distributional magnetic Hamiltonian system may be summarized as follows.

**Definition 5.1** (Nonholonomic Reduced Distributional magnetic Hamiltonian System) Assume that the 5-tuple $(T^*Q, G, \omega^B, \mathcal{D}, H)$ is a nonholonomic magnetic Hamiltonian system with symmetry, where $\omega^B$ is the magnetic symplectic form on $T^*Q$, and $\mathcal{D} \subset TQ$ is a $\mathcal{D}$-completely and $\mathcal{D}$-regularly nonholonomic constraint of the system, and $\mathcal{D}$ and $H$ are both $G$-invariant. If there exists a nonholonomic reduced distribution $\bar{\mathcal{K}}$, an associated non-degenerate and nonholonomic reduced distributional two-form $\omega^B_{\bar{K}}$ and a vector field $X^B_{\bar{K}}$ on the reduced constraint submanifold $\bar{M} = \mathcal{M}/G$, where $\mathcal{M} = \mathcal{F}(\mathcal{D}) \subset T^*Q$, such that the nonholonomic reduced distributional magnetic Hamiltonian equation $\iota_{X^B_{\bar{K}}} \omega^B_{\bar{K}} = \text{d} h_{\bar{K}}$ holds, where $\text{d} h_{\bar{K}}$ is the restriction of $\text{d} h_{\bar{M}}$ to $\bar{\mathcal{K}}$ and the function $h_{\bar{K}}$ satisfies $\text{d} h_{\bar{K}} = \tau_{\bar{K}} \cdot h_{\bar{M}}$ and $h_{\bar{M}} \cdot \pi/G = H_{\bar{\mathcal{M}}}$ as defined above. Then the triple $(\bar{\mathcal{K}}, \omega^B_{\bar{K}}, h_{\bar{K}})$ is called a nonholonomic reduced distributional magnetic Hamiltonian system of the
nonholonomic magnetic Hamiltonian system with symmetry \((T^*Q,G,\omega^B,D,H)\), and \(X^B_K\) is called a nonholonomic reduced dynamical vector field of the system \((\bar{K},\omega^B_K,h_{\bar{K}})\). Under the above circumstances, we refer to \((T^*Q,G,\omega^B,D,H)\) as a nonholonomic reducible magnetic Hamiltonian system with the associated distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,H_{\bar{K}})\) and nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\).

Since the non-degenerate and nonholonomic reduced distributional two-form \(\omega^B_K\) is not a "true two-form" on a manifold, and it is not symplectic, and hence the nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\) may not be yet a Hamiltonian system, and may have no generating function, and hence we cannot describe the Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system just like as in Theorem 1.1. But, since the nonholonomic reduced distributional magnetic Hamiltonian system is a dynamical system closely related to a magnetic Hamiltonian system, for a given nonholonomic reducible magnetic Hamiltonian system \((T^*Q,G,\omega^B,D,H)\) with the associated distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,H_{\bar{K}})\) and the nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\), by using Lemma 3.4 and Lemma 4.3, we can also derive precisely the geometric constraint conditions of the nonholonomic reduced distributional two-form \(\omega^B_K\) for the dynamical vector field \(X^B_K\), that is, the two types of Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system. For convenience, the maps involved in the following theorem and its proof are shown in Diagram-5.

\[
\begin{array}{c}
\mathcal{M} \xrightarrow{i_M} T^*Q \xrightarrow{\pi_Q} Q \xrightarrow{\gamma} T^*Q \xrightarrow{\pi_J/G} T^*Q/G \xleftarrow{i_M} \mathcal{M} \\
X^B_K \downarrow \bar{K} \xrightarrow{\tau_K} T(T^*Q) \xrightarrow{TQ} T^*Q \xleftarrow{TQ} T(T^*Q) \xrightarrow{T\pi_J/G} T(T^*Q/G) \xleftarrow{\bar{K}} \bar{K} \\
X^B_H \end{array}
\]

Diagram-5

**Theorem 5.2 (Type I of Hamilton-Jacobi Theorem for a Nonholonomic Reduced Distributional magnetic Hamiltonian System)** For a given nonholonomic reducible magnetic Hamiltonian system \((T^*Q,G,\omega^B,D,H)\) with the associated distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,H_{\bar{K}})\) and the nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\), assume that \(\gamma : Q \to T^*Q\) is an one-form on \(Q\), and \(X^\gamma = T\pi_Q \cdot X^B_H \cdot \gamma\), where \(X^B_H\) is the magnetic Hamiltonian vector field of the corresponding unconstrained magnetic Hamiltonian system with symmetry \((T^*Q,G,\omega^B,H)\). Moreover, assume that \(\text{Im}(\gamma) \subset M\), and it is \(G\)-invariant, \(\text{Im}(T\gamma) \subset \bar{K}\), and \(\bar{\gamma} = \pi_J/G(\gamma) : Q \to T^*Q/G\). If the one-form \(\gamma : Q \to T^*Q\) satisfies the condition that \(d\gamma = -B\) on \(D\) with respect to \(T\pi_Q : TT^*Q \to TQ\), then \(\bar{\gamma}\) is a solution of the equation \(T\bar{\gamma} \cdot X^{\bar{\gamma}} = X^B_K \cdot \bar{\gamma}\). Here \(X^B_K\) is the dynamical vector field of the nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\). The equation \(T\bar{\gamma} \cdot X^{\bar{\gamma}} = X^B_K \cdot \bar{\gamma}\), is called the Type I of Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system \((\bar{K},\omega^B_K,h_{\bar{K}})\).

**Proof:** At first, from Theorem 4.4, we know that \(\gamma\) is a solution of the Hamilton-Jacobi equation \(T\gamma \cdot X^\gamma = X^B_K \cdot \gamma\). Next, we note that \(\text{Im}(\gamma) \subset M\), and it is \(G\)-invariant, \(\text{Im}(T\gamma) \subset \bar{K}\), and hence \(\text{Im}(T\bar{\gamma}) \subset \bar{K}\), in this case, \(\pi_J/G(\omega^B_K) = \tau_M \cdot \omega^B_M = \tau_M \cdot i_M^* \omega^B, \) along \(\text{Im}(T\bar{\gamma})\). From the distributional magnetic Hamiltonian equation (2.2), we have that \(X^B_K = \tau_K \cdot X^B_H, \) and \(\tau_K \cdot X^B_H \cdot \gamma = X^B_K \cdot \gamma\). Because the vector fields \(X^B_K\) and \(X^B_H\) are \(\pi_J/G\)-related, \(T\pi_J/G(X^B_K) = X^B_K \cdot \pi_J/G, \) and hence
\[ \tau_{\mathcal{K}} \cdot T\pi_{/G}(X^{B}_{\mathcal{K}} \cdot \gamma) = \tau_{\mathcal{K}} \cdot (T\pi_{/G}(X^{B}_{\mathcal{K}})) \cdot (\gamma) = \tau_{\mathcal{K}} \cdot (X^{B}_{\mathcal{K}} \cdot \pi_{/G}) \cdot (\gamma) = \tau_{\mathcal{K}} \cdot X^{B}_{\mathcal{K}} \cdot \pi_{/G}(\gamma) = X^{B}_{\mathcal{K}} \cdot \gamma. \]

Thus, using the non-degenerate, nonholonomic reduced distributional two-form \( \omega^{B}_{\mathcal{K}} \), from Lemma 3.4(ii) and Lemma 4.3, if we take that \( v = X^{H}_{\mathcal{K}} \cdot \gamma \in \mathcal{F} \), and for any \( w \in \mathcal{F}, T\lambda(w) \neq 0 \), and \( \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w \neq 0 \), then we have that

\[ \omega^{B}_{\mathcal{K}}(T\gamma \cdot X^{\gamma}, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) = \omega^{B}_{\mathcal{K}}(\tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot X^{\gamma}, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) - \omega^{B}_{\mathcal{K}}(\tau_{\mathcal{K}} \cdot T\pi_{/G}(X^{B}_{\mathcal{K}}) \cdot \gamma, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) = \pi^{*}_{G} \cdot \omega^{B}_{\mathcal{K}}(T\gamma \cdot X^{\gamma}, \tau_{\mathcal{K}} \cdot T\pi_{/G}(X^{B}_{\mathcal{K}}) \cdot \gamma, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) - \omega^{B}_{\mathcal{K}}(\tau_{\mathcal{K}} \cdot T\pi_{/G}(X^{B}_{\mathcal{K}}) \cdot \gamma, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) \]

where we have used that \( \tau_{\mathcal{K}} \cdot T\pi_{/G}(X^{B}_{\mathcal{K}}) \cdot \gamma = \tau_{\mathcal{K}} \cdot X^{B}_{\mathcal{K}} \cdot \gamma = X^{B}_{\mathcal{K}} \cdot \gamma \), and \( \tau_{\mathcal{K}} \cdot T\gamma = T\gamma \), since \( \text{Im}(T\gamma) \subset \bar{\mathcal{K}} \).

Note that \( X^{B}_{\mathcal{K}} \cdot \gamma, w \in \mathcal{F} \), and \( T\pi_{Q}(X^{B}_{\mathcal{K}} \cdot \gamma), T\pi_{Q}(w) \in \mathcal{D} \). If the one-form \( \gamma : Q \to T^{*}Q \) satisfies the condition that \( (d\gamma + B)(T\pi_{Q}(X^{B}_{\mathcal{K}} \cdot \gamma), T\pi_{Q}(w)) = 0 \), and hence

\[ \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w \neq 0, \]

Thus, we have that

\[ \omega^{B}_{\mathcal{K}}(T\gamma \cdot X^{\gamma}, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) = \omega^{B}_{\mathcal{K}}(X^{B}_{\mathcal{K}} \cdot \gamma, \tau_{\mathcal{K}} \cdot T\pi_{/G} \cdot w) = -\omega^{B}_{\mathcal{K}}(X^{B}_{\mathcal{K}} \cdot \gamma, T\gamma \cdot T\pi_{Q}(w)). \] (5.3)

If \( \gamma \) satisfies the equation \( T\gamma \cdot X^{\gamma} = X^{B}_{\mathcal{K}} \cdot \gamma \), from Lemma 3.4(i) we know that the right side of (5.3) becomes that

\[ -\omega^{B}_{\mathcal{K}}(X^{B}_{\mathcal{K}} \cdot \gamma, T\gamma \cdot T\pi_{Q}(w)) = -\omega^{B}_{\mathcal{K}}(X^{B}_{\mathcal{K}} \cdot \gamma, T\gamma \cdot T\pi_{Q}(w)) \]

where \( \gamma^{*} \cdot \tau_{\mathcal{K}} \cdot i^{*}_{M} \cdot \omega^{B} = \tau_{\mathcal{K}} \cdot i^{*}_{M} \cdot \gamma^{*} \cdot \omega^{B} \), because \( \text{Im}(\gamma) \subset \mathcal{M} \). But, since the nonholonomic reduced distributional two-form \( \omega^{B}_{\mathcal{K}} \) is non-degenerate, the left side of (5.3) equals zero, only when \( \gamma \) satisfies the equation \( T\gamma \cdot X^{\gamma} = X^{B}_{\mathcal{K}} \cdot \gamma \). Thus, if the one-form \( \gamma : Q \to T^{*}Q \) satisfies the condition that \( d\gamma = -B \) on \( \mathcal{D} \) with respect to \( T\pi_{Q} : TT^{*}Q \to TQ \), then \( \gamma \) must be a solution of the Type I of
Hamilton-Jacobi equation $T\gamma \cdot X\gamma = X^B_K \cdot \tilde{\gamma}$.

Next, for any $G$-invariant symplectic map $\varepsilon : T^*Q \to T^*Q$ with respect to $\omega^B$, we can prove the following Type II of Hamilton-Jacobi theorem for the nonholonomic reduced distributional magnetic Hamiltonian system. For convenience, the maps involved in the following theorem and its proof are shown in Diagram-6.

\[M \xrightarrow{i_M} T^*Q \xrightarrow{\pi_Q} T^*Q \xrightarrow{\gamma} T^*Q \overset{\pi/G}{\longrightarrow} T^*Q/G \overset{i_{\tilde{M}}}{\longleftarrow} \bar{M}
\]

\[\mathcal{K} \xrightarrow{T(T^*Q)} TQ \overset{T\pi_Q}{\longrightarrow} T(T^*Q) \overset{T\pi/G}{\longrightarrow} T(T^*Q/G) \overset{T\tau}{\longleftarrow} \mathcal{K}
\]

Diagram-6

**Theorem 5.3 (Type II of Hamilton-Jacobi Theorem for a Nonholonomic Reduced Distributional Magnetic Hamiltonian System)** For a given nonholonomic reducible magnetic Hamiltonian system $(T^*Q, G, \omega^B, \mathcal{D}, H)$ with the associated distributional magnetic Hamiltonian system $(\mathcal{K}, \omega^B_K, H_K)$ and the nonholonomic reduced distributional magnetic Hamiltonian system $(\bar{K}, \omega^B_{\bar{K}}, h_{\bar{K}})$, assume that $\gamma : Q \to T^*Q$ is an one-form on $Q$, and $\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q$, and for any $G$-invariant symplectic map $\varepsilon : T^*Q \to T^*Q$ with respect to $\omega^B$, denote by $X^\varepsilon = T\pi_Q \cdot X^B_{\varepsilon} \cdot \varepsilon$, where $X^B_{\varepsilon}$ is the magnetic Hamiltonian vector field of the corresponding unconstrained magnetic Hamiltonian system with symmetry $(T^*Q, G, \omega^B, H)$. Moreover, assume that $\text{Im}(\gamma) \subset M$, and it is $G$-invariant, $\varepsilon(M) \subset M$, $\text{Im}(T\gamma) \subset K$, and $\bar{\gamma} = \pi_G(\gamma) : Q \to T^*Q/G$, and $\lambda = \pi_G(\lambda) : T^*Q \to T^*Q/G$, and $\bar{\varepsilon} = \pi_G(\varepsilon) : T^*Q \to T^*Q/G$. Then $\varepsilon$ and $\bar{\varepsilon}$ satisfy the equation $T\bar{\gamma} \cdot X^\varepsilon = X^B_{\bar{K}} \cdot \bar{\varepsilon}$. Here $X^B_{\bar{K}} \cdot \bar{\varepsilon}$ is the magnetic Hamiltonian vector field of the function $h_{\bar{K}} \cdot \bar{\varepsilon} : T^*Q \to \mathbb{R}$, and $X^B_{\bar{K}}$ is the dynamical vector field of the nonholonomic reduced distributional magnetic Hamiltonian system $(\bar{K}, \omega^B_{\bar{K}}, h_{\bar{K}})$. The equation $T\bar{\gamma} \cdot X^\varepsilon = X^B_{\bar{K}} \cdot \bar{\varepsilon}$, is called the Type II of Hamilton-Jacobi equation for the nonholonomic reduced distributional magnetic Hamiltonian system $(\bar{K}, \omega^B_{\bar{K}}, h_{\bar{K}})$.

**Proof:** In the same way, we note that $\text{Im}(\gamma) \subset M$, and it is $G$-invariant, $\text{Im}(T\gamma) \subset K$, and hence $\text{Im}(T\bar{\gamma}) \subset \bar{K}$, in this case, $\pi^*_G \cdot \omega^B_K \cdot \tau_{\bar{K}} = \tau_{\bar{U}} \cdot \omega^B_K = \tau_{\bar{U}} \cdot i_{\bar{M}} \cdot \omega^B_K$, along $\text{Im}(T\bar{\gamma})$. Moreover, from the distributional magnetic Hamiltonian equation (2.2), we have that $X^B_K \cdot \tau_{\bar{K}} = X^B_K \cdot \pi^*_G \cdot \varepsilon$. Note that $\varepsilon(M) \subset M$, and $T\pi_Q(X^B_H \cdot \varepsilon(q, p)) \in \mathcal{D}_q, \forall q \in Q, (q, p) \in M(\subset T^*Q)$, and hence $X^B_H \cdot \varepsilon \in \mathcal{F}$ along $\varepsilon$. Because the vector fields $X^B_K$ and $X^B_H$ are $\pi^*_G$-related, $T\pi^*_G(X^B_K) = X^B_K \cdot \pi^*_G$, and hence $T\pi^*_G(X^B_H \cdot \varepsilon) = \pi_G \cdot (T\pi^*_G(X^B_K)) \cdot (\varepsilon) = \pi_G \cdot (X^B_K \cdot \pi^*_G \cdot (\varepsilon) = \pi_G \cdot \tau_{\bar{K}} \cdot \varepsilon = \tau_{\bar{K}} \cdot \bar{\varepsilon}$. Thus, using the non-degenerate and nonholonomic reduced distributional two-form $\omega^B_K$, from Lemma 3.4 and Lemma 4.3, if we take that $v = X^B_H \cdot \varepsilon \in \mathcal{F}$, and for any $w \in \mathcal{F}$, $T\lambda(w) \neq 0$, and $\tau_{\bar{K}} \cdot T\pi^*_G \cdot w \neq 0$,
then we have that

\[
\omega^B_K(T\gamma \cdot X^e, \tau_K \cdot T\pi_{/G} \cdot w) = \omega^B_K(\tau_K \cdot T(\pi_{/G} \cdot \gamma) \cdot X^e, \tau_K \cdot T\pi_{/G} \cdot w)
\]

\[
= \pi^*_G \cdot \omega^B_K \cdot \tau_K(T\gamma \cdot X^e, \tau_K \cdot T\pi_{/G} \cdot w) = \tau_K \cdot i^*_M \cdot \omega^B(\tau_K \cdot T(\gamma \cdot X^e, \tau_K \cdot T\pi_{/G} \cdot w)
\]

\[
= \tau_K \cdot i^*_M \cdot \omega^B(T(\gamma \cdot \pi_Q) \cdot X^e, \tau_K \cdot T\pi_{/G} \cdot w)
\]

\[
= \tau_K \cdot i^*_M \cdot (\omega^B(X^e_H \cdot \varepsilon, w - T(\gamma \cdot \pi_Q) \cdot w) - (d\gamma + B)(T\pi_Q(X^e_H \cdot \varepsilon), T\pi_Q(w)))
\]

\[
= \tau_K \cdot i^*_M \cdot \omega^B(X^e_H \cdot \varepsilon, w - \tau_K \cdot i^*_M \cdot \omega^B(X^e_H \cdot \varepsilon, w, T\lambda \cdot w)
\]

\[
- \tau_K \cdot i^*_M \cdot (d\gamma + B)(T\pi_Q(X^e_H \cdot \varepsilon), T\pi_Q(w))
\]

\[
= \pi^*_G \cdot \omega^B_K \cdot \tau_K(X^e_H \cdot \varepsilon, w) - \pi^*_G \cdot \omega^B_K \cdot \tau_K(X^e_H \cdot \varepsilon, T\lambda \cdot w) + \tau_K \cdot i^*_M \cdot \lambda^w(B(X^e_H \cdot \varepsilon, w)
\]

\[
= \omega^B_K(\tau_K \cdot T\pi_{/G}(X^e_H \cdot \varepsilon), \tau_K \cdot T\pi_{/G} \cdot \omega^B_K(\tau_K \cdot T\pi_{/G}(X^e_H \cdot \varepsilon), \tau_K \cdot T(\pi_{/G} \cdot \lambda) \cdot w)
\]

\[
+ \pi^*_G \cdot \omega^B_K \cdot \tau_K(T\lambda \cdot X^e_H \cdot \varepsilon, T\lambda \cdot w)
\]

\[
= \omega^B_K(\tau_K \cdot T\pi_{/G}(X^e_H \cdot \varepsilon), \tau_K \cdot T\pi_{/G} \cdot \omega^B_K(\tau_K \cdot T\pi_{/G}(X^e_H \cdot \varepsilon), \tau_K \cdot T\pi_{/G} \cdot \lambda) \cdot w)
\]

\[
+ \omega^B_K(\tau_K \cdot T\pi_{/G} \cdot \lambda \cdot X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \lambda \cdot T\lambda \cdot w)
\]

\[
= \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \lambda \cdot T\lambda \cdot w)
\]

\[
= \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \lambda \cdot T\lambda \cdot w)
\]

\[
= \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \omega^B_K(X^e_H \cdot \varepsilon, \tau_K \cdot T\pi_{/G} \cdot \lambda \cdot T\lambda \cdot w)
\]

\[
= \omega^B_K(T\lambda \cdot X^e_H \cdot \varepsilon - \tau_K \cdot T\varepsilon \cdot X^B_{h_K \cdot \varepsilon}, T\lambda \cdot w).
\]

Because the nonholonomic reduced distributional two-form \(\omega^B_K\) is non-degenerate, it follows that the equation \(T\gamma \cdot X^e = X^B_K \cdot \varepsilon\), is equivalent to the equation \(T\lambda \cdot X^e_H \cdot \varepsilon = \tau_K \cdot T\varepsilon \cdot X^B_{h_K \cdot \varepsilon}\). Thus, \(\varepsilon\) and \(\varepsilon\) satisfy the equation \(T\lambda \cdot X^e_H \cdot \varepsilon = \tau_K \cdot T\varepsilon \cdot X^B_{h_K \cdot \varepsilon}\), if and only if they satisfy the Type II of Hamilton-Jacobi equation \(T\gamma \cdot X^e = X^B_K \cdot \varepsilon\). □

For a given nonholonomic reducible magnetic Hamiltonian system \((T^*Q, \mathcal{G}, \omega^B, \mathcal{D}, H)\) with the associated distributional magnetic Hamiltonian system \((K, \omega^B_K, H_K)\) and the nonholonomic reduced distributional magnetic Hamiltonian system \((\hat{K}, \omega^B_{\hat{K}}, h_{\hat{K}})\), we know that the nonholonomic dynamical vector field \(X^\hat{K}_K\) and the nonholonomic reduced dynamical vector field \(X^\hat{K}_K\) are \(\pi_{/G}\)-related, that is, \(X^\hat{K}_K \cdot \pi_{/G} = T\pi_{/G} \cdot X^\hat{K}_K\). Then we can prove the following Theorem 5.4, which states the relationship between the solutions of Type II of Hamilton-Jacobi equations and nonholonomic reduction.

**Theorem 5.4** For a given nonholonomic reducible magnetic Hamiltonian system \((T^*Q, \mathcal{G}, \omega^B, \mathcal{D}, H)\) with the associated distributional magnetic Hamiltonian system \((K, \omega^B_K, H_K)\) and the nonholonomic reduced distributional magnetic Hamiltonian system \((\hat{K}, \omega^B_{\hat{K}}, h_{\hat{K}})\), assume that \(\gamma : Q \to T^*Q\) is an one-form on \(Q\), and \(\lambda = \gamma \cdot \pi_Q : T^*Q \to T^*Q\), and \(\varepsilon : T^*Q \to T^*Q\) is a \(G\)-invariant symplectic map with respect to \(\omega^B\). Moreover, assume that \(\text{Im}(\gamma) \subset M\), and it is \(G\)-invariant, \(\varepsilon(M) \subset M\), \(\text{Im}(T\gamma) \subset K\), and \(\tilde{\gamma} = \pi_{/G}(\gamma) : Q \to T^*Q/G\), and \(\tilde{\lambda} = \pi_{/G}(\lambda) : T^*Q \to T^*Q/G\), and \(\tilde{\varepsilon} = \pi_{/G}(\varepsilon) : T^*Q \to T^*Q/G\). Then \(\varepsilon\) is a solution of the Type II of Hamilton-Jacobi equation,
$T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, for the distributional magnetic Hamiltonian system $(\mathcal{K}, \omega^K_B, H_K)$, if and only if $\varepsilon$ and $\bar{\varepsilon}$ satisfy the Type II of Hamilton-Jacobi equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, for the nonholonomic reduced distributional magnetic Hamiltonian system $(\bar{\mathcal{K}}, \omega^K_B, h_K)$.

**Proof:** Note that $\text{Im}(\gamma) \subset \mathcal{M}$, and it is $G$-invariant, $\text{Im}(T\gamma) \subset \mathcal{K}$, and hence $\text{Im}(T\bar{\gamma}) \subset \bar{\mathcal{K}}$, in this case, $\pi^*_{/G} \cdot \omega^K_B = \tau_B \cdot \omega^B_{\mathcal{M}} = \tau_B \cdot i^*_{\mathcal{M}} \cdot \omega^B = \omega^K_B \cdot \tau_B$, along $\text{Im}(T\gamma)$, and $\tau_B \cdot T\gamma = T\bar{\gamma}$, $\tau_B \cdot X^K_B = X^K_B$. Since nonholonomic vector field $X^K_B$ and the vector field $X^K_B$ are $\pi^*_{/G}$-related, that is, $X^K_B \pi^*_{/G} = T\pi^*_{/G} X^K_B$, using the non-degenerate and nonholonomic reduced distributional two-form $\omega^K_B$, we have that

$$
\omega^K_B (T\gamma \cdot X^\varepsilon - X^K_B \cdot \varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w) = \omega^K_B (T\gamma \cdot X^\varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w) - \omega^K_B (X^K_B \cdot \varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w)
$$

In the case we considered that $\pi^*_{/G} \cdot \omega^K_B = \tau_K \cdot i^*_{\mathcal{M}} \cdot \omega^B = \omega^K_B \cdot \tau_K$, and $\tau_B \cdot T\gamma = T\gamma$, $\tau_B \cdot X^K_B = X^K_B$, since $\text{Im}(\gamma) \subset \mathcal{M}$, and $\text{Im}(T\gamma) \subset \bar{\mathcal{K}}$. Thus, we have that

$$
\omega^K_B (T\gamma \cdot X^\varepsilon - X^K_B \cdot \varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w) = \omega^K_B (T\gamma \cdot X^\varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w) - \omega^K_B (X^K_B \cdot \varepsilon, \tau_B \cdot T\pi^*_{/G} \cdot w).
$$

Because the distributional two-form $\omega^K_B$ and the nonholonomic reduced distributional two-form $\omega^K_B$ are both non-degenerate, it follows that the equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, is equivalent to the equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$. Thus, $\varepsilon$ is a solution of the Type II of Hamilton-Jacobi equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, for the distributional magnetic Hamiltonian system $(\mathcal{K}, \omega^K_B, H_K)$, if and only if $\varepsilon$ and $\bar{\varepsilon}$ satisfy the Type II of Hamilton-Jacobi equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, for the nonholonomic reduced distributional magnetic Hamiltonian system $(\bar{\mathcal{K}}, \omega^K_B, h_K)$.

**Remark 5.5** It is worthy of noting that, the Type I of Hamilton-Jacobi equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, is the equation of the nonholonomic reduced differential one-form $\gamma$; and the Type II of Hamilton-Jacobi equation $T\gamma \cdot X^\varepsilon = X^K_B \cdot \varepsilon$, is the equation of the symplectic diffeomorphism map $\varepsilon$ and the nonholonomic reduced symplectic diffeomorphism map $\bar{\varepsilon}$. When $B = 0$, in this case the magnetic symplectic form $\omega^K_B$ is just the canonical symplectic form $\omega$ on $T^*Q$, and the nonholonomic reducible magnetic Hamiltonian system is just the nonholonomic reducible Hamiltonian system itself, and the nonholonomic reduced distributional magnetic Hamiltonian system is just the nonholonomic reduced distributional Hamiltonian system. From the above Type I and Type II of Hamilton-Jacobi theorems, that is, Theorem 5.2 and Theorem 5.3, we can get the Theorem 4.2 and Theorem 4.3 given in León and Wang [14]. It shows that Theorem 5.2 and Theorem 5.3 can be regarded as an extension of two types of Hamilton-Jacobi theorem for the nonholonomic reduced distributional Hamiltonian system to that for the nonholonomic reduced distributional magnetic Hamiltonian system.

In order to describe the impact of different geometric structures and constraints for the dynamics of a Hamiltonian system, in this paper, we study the Hamilton-Jacobi theory for the magnetic Hamiltonian system, the nonholonomic magnetic Hamiltonian system and the nonholonomic reducible magnetic Hamiltonian system on a cotangent bundle, by using the distributional magnetic
Hamiltonian system and the nonholonomic reduced distributional magnetic Hamiltonian system, which are the development of the Hamilton-Jacobi theory for the nonholonomic Hamiltonian system and the nonholonomic reducible Hamiltonian system given in León and Wang [14]. These research works reveal from the geometrical point of view the internal relationships of the magnetic symplectic form, nonholonomic constraint, non-degenerate distributional two form and dynamical vector fields of a nonholonomic magnetic Hamiltonian system and the nonholonomic reducible magnetic Hamiltonian system. It is worthy of noting that, Marsden et al. in [20] set up the regular reduction theory of regular controlled Hamiltonian systems on a symplectic fiber bundle, by using momentum map and the associated reduced symplectic forms, and from the viewpoint of completeness of Marsden-Weinstein symplectic reduction, and some developments around the above work are given in Wang and Zhang [32], Ratiu and Wang [24], and Wang [25–28]. Since the Hamilton-Jacobi theory is developed based on the Hamiltonian picture of dynamics, it is natural idea to extend the Hamilton-Jacobi theory to the (regular) controlled (magnetic) Hamiltonian systems and their a variety of reduced systems, and it is also possible to describe the relationship between the RCH-equivalence for controlled Hamiltonian systems and the solutions of corresponding Hamilton-Jacobi equations, see Wang [29–31] for more details. Thus, our next topic is how to set up and develop the nonholonomic reduction and Hamilton-Jacobi theory for the nonholonomic controlled (magnetic) Hamiltonian systems and the distributional controlled (magnetic) Hamiltonian systems, by analyzing carefully the geometrical and topological structures of the phase spaces of these systems. It is the key thought of the researches of geometrical mechanics of the professor Jerrold E. Marsden to explore and reveal the deeply internal relationship between the geometrical structure of phase space and the dynamical vector field of a mechanical system. It is also our goal of pursuing and inheriting. In addition, we note also that there have been a lot of beautiful results of reduction theory of Hamiltonian systems in celestial mechanics, hydrodynamics and plasma physics. Thus, it is an important topic to study the application of reduction theory and Hamilton-Jacobi theory of the systems in celestial mechanics, hydrodynamics and plasma physics. These are our goals in future research.

Acknowledgments: The year of 2021 is S.S. Chern’s year of Nankai University in China, for the 110th anniversary of the birth of Professor S.S. Chern. Shiing Shen Chern (1911-10-28—2004-12-03) is a great geometer and a model of excellent scientists. All of the differential geometry theory and methods for us used in the research of geometrical mechanics, are studied from his books and his research papers. He is a good example of us learning from him forevermore.
