MDS and AMDS symbol-pair codes are constructed from repeated-root codes

Xiuxin Tang, Rong Luo

Abstract

Symbol-pair codes introduced by Cassuto and Blaum in 2010 are designed to protect against the pair errors in symbol-pair read channels. One of the central themes in symbol-error correction is the construction of maximal distance separable (MDS) symbol-pair codes that possess the largest possible pair-error correcting performance. In this paper, we construct more general generator polynomials for two classes of MDS symbol-pair codes with code length \(lp\). Based on repeated-root cyclic codes, we derive all MDS symbol-pair codes of length \(3p\), when the degree of the generator polynomials is no more than 10. We also give two new classes of (almost maximal distance separable) AMDS symbol-pair codes with the length \(lp\) or \(4p\) by virtue of repeated-root cyclic codes. For length \(3p\), we derive all AMDS symbol-pair codes, when the degree of the generator polynomials is less than 10. The main results are obtained by determining the solutions of certain equations over finite fields.

Keywords: MDS symbol-pair codes, AMDS symbol-pair codes, Minimum symbol-pair distance, Repeated-root cyclic codes

1. Introduction

With the development of high-density data storage technologies, a new coding framework called symbol-pair codes was proposed by Cassuto and Blaum (2010) to combat symbol-pair-errors over symbol-pair read channels in [1]. The seminal works [1]–[3] have established relationships between the minimum Hamming distance of an error-correcting code and the minimum symbol-pair distance, have found methods for code constructions and decoding, and have obtained lower and upper bounds on code size. If a code \(C\) over \(\mathbb{F}_p^n\) of length \(n\) contains \(M\) elements and has the minimum symbol-pair distance \(d_p\), then \(C\) is referred as an \((n, M, d_p)\) symbol-pair code. Finding symbol-pair codes with high symbol-pair error correcting performance has become a great challenge in the theory. Therefore, we wish to obtain symbol-pair codes that possess minimum symbol-pair distance as large as possible.

In 2012, Chee et al. [4] established the Singleton-type bound on symbol-pair codes. Similar to the classical codes, the symbol-pair codes meeting the Singleton-type bound are called MDS symbol-pair codes. Due to the optimality, MDS symbol-pair codes are the most useful and
interesting symbol-pair codes. Many researchers attempted to obtain MDS symbol-pair codes by different mathematical tools. Constructing MDS symbol-pair codes is thus of significance in theory and practice. However, not much work has been done on determining the exact values of symbol-pair distances of constacyclic codes as it is a very complicated and difficult task in general.

In 2013, Chee et al. [5] obtained some MDS symbol-pair codes from classical MDS codes. Between 2015 and 2018, researchers [6][7][8] constructed some MDS symbol-pair codes with minimum symbol-pair distance 5 and 6 from constacyclic codes. In 2017, Chen et al. [9] proposed to construct MDS symbol-pair codes by repeated-cyclic codes and obtained some length 3p MDS symbol-pair codes with symbol-pair distance 6 to 8 and MDS \((l p,5)_p\) symbol-pair codes. In the next few years, MDS symbol-pair codes with some new parameters were found by using repeated-root codes over \(\mathbb{F}_{p}\). In 2018, Kai et al. [8] proved the existence of an MDS \((4p,7)_p\) symbol-pair code. In the same year, Dinh et al. [10] presented all MDS symbol-pair codes of prime power lengths by repeated-root constacyclic codes. In 2019, Zhao [11] gave an MDS \((l p,6)_p\) symbol-pair code. In 2020, Dinh et al. [12] constructed a families of MDS symbol-pair codes with length \(2^p\), where \(g_{i,j} = (x-1)(x+1)\) is expressed as the generator polynomials of these codes and \(|i-j| \leq 2\). In 2021, Ma et al. [13] obtained MDS \((3p,10)_p\) and MDS \((3p,12)_p\) symbol-pair codes.

Inspired by these works, in order to obtain longer and more flexible symbol-pair codeword length, as well as a larger minimum symbol-pair distance, this paper proves that there are more general generator polynomials for MDS \((l p,6)_p\) and MDS \((l p,5)_p\) symbol-pair codes by using repeated-cyclic codes. For length \(n = 3p\), this paper gives all MDS symbol-pair codes from repeated-root cyclic codes \(C_{r1r2r3}\), when the degree of the generator polynomial \(g_{r1r2r3}(x)\) is no more than 10, i.e \(\deg(g(x)) \leq 10\). Furthermore, the parameters of AMDS \((4p,8)_p\) and AMDS \((l p,7)_p\) symbol-pair codes are obtained by using repeated-cyclic codes. For length \(3p\), this paper also obtains all AMDS symbol-pair codes from repeated-root cyclic codes \(C_{r1r2r3}\), when \(\deg(g(x)) \leq 10\).

The remainder of this paper is organized as follows. In Section 2, we introduce some basic notations and auxiliary tools on symbol-pair codes. In Section 3, on the basis of repeated-root cyclic codes, we derive some new classes of MDS symbol-pair codes and new classes of AMDS symbol-pair codes. In section 4, we conclude the paper.

2. Preliminaries

In this section, we introduce some notations and auxiliary tools on symbol-pair codes, which will be used to prove our main results in the sequel. Let

\[ x = (x_0,x_1,\cdots,x_{n-1}) \]

be a vector in \(\mathbb{F}_p^n\). Then the symbol-pair read vector of \(x\) is

\[ \pi(x) = [(x_0,x_1),(x_1,x_2),\cdots,(x_{n-1},x_0)]. \]

Similar to the Hamming weight \(\omega_H(x)\) and Hamming distance \(D_H(x,y)\). The symbol-pair weight \(\omega_p(x)\) of the symbol-pair vector \(x\) is defined as

\[ \omega_p(x) = |\{i|(x_i,x_{i+1}) \neq (0,0)\}|. \]
The symbol-pair distance $D_p(x, y)$ between any two vectors $x, y$ is

$$D_p(x, y) = |\{ i \mid (x_i, x_{i+1}) \neq (y_i, y_{i+1}) \}|.$$  

The minimum symbol-pair distance of a code $C$ is

$$d_p = \min \{ D_p(x, y) \mid x, y \in C \},$$

and we denote $(n, k, d_p)_p$ a symbol-pair code with length $n$, dimension $k$ and minimum symbol-pair distance $d_p$ over $\mathbb{F}_p$.

In this paper, we always regard the codeword $c$ in $C$ as the corresponding polynomial $c(x)$. We denote that $\mathbb{F}_p$ and $\mathbb{F}_q$ are finite fields, where $p$ is an odd prime and $q = p^m$. The following lemmas will be applied in our later proofs.

In contrast to the classical error-correcting codes, the size of a symbol-pair code satisfies the following Singleton bound. The symbol-pair code achieving the Singleton bound is called a maximum distance separable (MDS) symbol-pair code.

**Lemma 2.1.** (4) If $C$ is a symbol-pair code with length $n$ and minimum symbol-pair distance $d_p$ over $\mathbb{F}_q$, we call an $(n, d_p)_p$ symbol-pair code of size $q^{n-d_p+2}$ maximum distance separable (MDS) and an $(n, d_p)_p$ symbol-pair code of size $q^{n-d_p+1}$ almost maximum distance separable (AMDS) for $q \geq 2$.

**Lemma 2.2.** (5) Let $q \geq 2$ and $2 \leq d_p \leq n$. If $C$ is a symbol-pair code with length $n$ and minimum symbol-pair distance $d_p$ over $\mathbb{F}_q$, then $|C| \leq q^{n-d_p+2}$.

The next lemma is known MDS symbol-pair codes, which will be used by the later proof of Theorem 3.19.

**Lemma 2.3.** (8) Let $n = 4p$ with $p \equiv 3 \pmod{4}$. If $C$ is the cyclic code in $\mathbb{F}_p[x]/\langle x^n - 1 \rangle$ generated by

$$g(x) = (x-1)^3(x^2+1),$$

then we have $d_H = 4$ and $d_p = 7$. $C$ is an MDS $(4p, 7)_p$ symbol-pair code.

In some cases, the bound of minimum symbol-pair distance can be improved.

**Lemma 2.4.** (8) Let $C$ be an $[n, k, d_H]$ constacyclic code over $\mathbb{F}_q$ with $2 \leq d_H \leq n$. Then we have the following $d_p(C) \geq d_H + 2$ if and only if $C$ is not an MDS code.

The next lemma is known MDS symbol-pair code, which will be used by the later proof of Proposition 3.10.

**Lemma 2.5.** (8) Let $n = 3p$ with $p \equiv 1 \pmod{3}$. If $C$ is the cyclic code in $\mathbb{F}_p[x]/\langle x^n - 1 \rangle$ generated by

$$g(x) = (x-1)^3(x-\omega^2),$$

then we have $C$ is an MDS $(3p, 8)_p$ symbol-pair code, where $\omega$ is a primitive 3-th root of unity in $\mathbb{F}_p$.

Researchers constructed some MDS symbol-pair codes with minimum symbol-pair distance 6 by repeated-root cyclic codes. The following three lemmas are known MDS symbol-pair codes with minimum symbol-pair distance 6. These three lemmas will be used as several parts of Theorem 3.1.
Lemma 2.6. \(\text{(12)}\) C is an MDS symbol-pair code, when \((r_1, r_2, r_3) = (4, 0, 0)\) is satisfied. C is not an MDS symbol-pair code, when we have \((r_1, r_2, r_3) = (0, 4, 0), (0, 0, 4)\).

Lemma 2.7. \(\text{(17)}\) \(C = \left\langle (x-1)^3(x-\omega) \right\rangle\) is an MDS \((lp, 6)\) symbol-pair code with minimum pair-distance \(d_P = 6\) over \(\mathbb{F}_p\), where \(\omega\) is a primitive \(l\)-th root of unity in \(\mathbb{F}_p\).

Lemma 2.8. \(\text{(12)}\) \(C = \left\langle (x-1)^i(x+1)^j \right\rangle\) is an MDS symbol-pair code with minimum symbol-pair distance \(d_P = 6\) over \(\mathbb{F}_p\), where \(|i-j| \leq 2\) and \(i, j \leq p - 1\).

The following lemma gives the method to calculate of minimum Hamming distance about repeated-cyclic codes.

Lemma 2.9. \(\text{(12)}\) Let \(C\) be a repeated-root cyclic code of length \(lp^e\) over \(\mathbb{F}_q\) generated by \(g(x) = \prod m_i^{e_i}(x)\), where \(l\) and \(e\) are positive integers with \(\gcd(l, p) = 1\). Then we have

\[
d_H(C) = \min \{ P_t \cdot d_H(\overline{C}_t) | 0 \leq t \leq lp^e \},
\]

where \(P_t = \omega_H((x-1)^t)\) and \(\overline{C}_t = \left\langle \prod_{i=1}^{t} m_i(x) \right\rangle\).

3. Constructions of MDS and AMDS Symbol-Pair Codes

In this section, \(p\) is an odd prime and \(\mathbb{F}_p\) is a \(p\)-ary finite field. All symbol-pair codes are constructed by repeated-root cyclic codes.

For MDS symbol-pair codes, we construct more general generator polynomials with code length \(lp\). We also derive all MDS symbol-pair codes of length 3p, when \(\deg(g(x)) \leq 10\).

For AMDS symbol-pair codes, we propose two new classes of AMDS symbol-pair codes from repeated-root cyclic codes by analyzing the solutions of certain equations over \(\mathbb{F}_p\). We also obtain all AMDS symbol-pair codes of length 3p, when \(\deg(g(x)) \leq 10\).

3.1. MDS Symbol-Pair Codes of length \(lp\)

In this subsection, we prove that there exists more general generator polynomials about MDS \((lp, 6)_p\) and MDS \((lp, 5)_p\) symbol-pair codes.

For preparation, we define the following notation. Let \(m_1\) and \(m_2\) be the element of \(\mathbb{F}_p\), then \(\text{lcm}[m_1, m_2]\) represents the lowest common multiple of \(m_1\) and \(m_2\) and \(\gcd(m_1, m_2)\) represents the greatest common divisor of \(m_1\) and \(m_2\).

Let \(C\) be the cyclic codes in \(\mathbb{F}_p[x]/(x^n - 1)\) and the generator polynomial of \(C\) is

\[
g(x) = (x-1)^{r_1} (x+1)^{r_2} (x-\omega)^{r_3},
\]

where \(\omega\) is a primitive \(l\)-th root of unity in \(\mathbb{F}_p\) and \(r_1 + r_2 + r_3 = 4\). Dinh \(\text{[10] [12]}\) discussed all cases of \(l = 1\) and \(l = 2\), here we focus on the case of \(l > 2\).

Theorem 3.1. \(\text{C} is an MDS symbol-pair code with minimum symbol-pair distance \(d_P = 6\), if \(r_1, r_2 and r_3 meet the conditions in Table\(\text{[7]}\).\)

The proof of Theorem\(\text{[3.1]}\) needs the following three propositions. For the case of generator polynomials with three factors \((x-1), (x+1)\) and \((x-\omega)\), we have the following proposition.
Table 1: MDS symbol-pair codes of Theorem 3.1

</table>

When $l$ even, $(klp, 6)_p$ means that $(klp, 6)_p = (lp, 6)_p$.
When $l$ odd, $(klp, 6)_p$ means that $(klp, 6)_p = (2lp, 6)_p$.

**Proposition 3.2.** $C$ is an MDS symbol-pair code with $d_p = 6$, if one of $(r_1, r_2, r_3) = (2, 1, 1)$, $(1, 2, 1)$ and $(1, 1, 2)$ is satisfied.

**Proof.** When $(r_1, r_2, r_3) = (2, 1, 1)$, let $C$ be the cyclic code in $\mathbb{F}_p[x]/\langle x^n - 1 \rangle$ and generated by $g(x) = (x - 1)^2(x + 1)(x - \omega)$.

By Lemma 2.9, let $\overline{g}_t(x)$ be the generator polynomials of $C_t$.

- If $t = 0$, then we have $\overline{g}_0(x) = (x - 1)(x + 1)(x - \omega)$.
  It is easy to verify that the minimum Hamming distance is 3 in $C_0$ and $P_0 = 1$. Therefore, this indicates $P_0 \cdot d_H(C_0) = 3$.
- If $t = 1$, then we have $\overline{g}_1(x) = (x - 1)$ and $P_1 = 2$. Thus, one can derive that $P_1 \cdot d_H(C_1) = 4$.
- If $2 \leq t \leq p - 1$, then we have $\overline{g}_t(x) = 1$ and $P_t \geq 2$. This implies that $P_t \cdot d_H(C_t) \geq 3$.
  Therefore, it can be verified that $C$ is an $[lp, lp - 4, 3]$ repeated-root cyclic code over $\mathbb{F}_p$. Lemma 2.4 yields that $d_p \geq 5$, since $C$ is not an MDS cyclic code.

1. If $c \in C$ has $\omega_p = 5$ with $\omega_H = 4$, then its certain cyclic shift must have the form
   $$(\ast, \ast, \ast, \ast, 0_s),$$
   where each $\ast$ denotes an element in $\mathbb{F}_p^6$ and $0_s$ is all-zero vector. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that
   $$c(x) = 1 + a_1 x + a_2 x^2 + a_3 x^3,$$
   then this leads to $\deg(c(x)) = 3 < 4 = \deg(g(x))$.
2. If $c \in C$ has $\omega_p = 5$ with $\omega_H = 3$, then its certain cyclic shift must have the form
   $$(\ast, \ast, 0_{s_1}, \ast, 0_{s_2}),$$
where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_{s_1}, 0_{s_2}$ are all-zero vectors. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that

$$c(x) = 1 + a_1 x + a_2 x'^t.$$ 

When $t$ even, it can be verified that

$$\begin{cases} 1 + a_1 + a_2 = 0, \\ 1 - a_1 + a_2 = 0, \end{cases}$$

since $c(1) = c(-1) = 0$. Then one can derive that $2a_1 = 0$, which is impossible, since $a_1 \neq 0$ and $2 \neq 0$.

Similarly, if $t$ odd, one can obtain that $2a_2 = 0$, which contradicts $p$ odd.

Let $y = -x, z = \frac{x}{\omega}$. For the generator polynomial $g_{r_1r_2r_3}(x)$ of $C_{r_1r_2r_3}$, we can deduce the following results by deforming it,

$$g_{211}(x) = (x - 1)^2(x + 1)(x - \omega) = (y + 1)^2(y - 1)(y + \omega) = g_{121}(y) = \omega^4(z - \frac{1}{\omega})^2(z + \frac{\omega}{\omega})(z - \frac{\omega}{\omega}) = \omega^4 g_{112}(z).$$

When $(r_1, r_2, r_3) = (1, 2, 1)$ and $(1, 1, 2)$, it is equivalent to $(r_1, r_2, r_3) = (2, 1, 1)$.

We have the following two propositions for generator polynomials only two of these three factors $(x - 1), (x + 1)$ and $(x - \omega)$.

**Proposition 3.3.** $C$ is an MDS symbol-pair code with $d_p = 6$, if one of $(r_1, r_2, r_3) = (1, 0, 3), (0, 3, 1)$ and $(0, 1, 3)$ is satisfied.

**Proof.** When $(r_1, r_2, r_3) = (1, 0, 3)$, let $C$ be a cyclic code in $\mathbb{F}_p[x]/(x^6 - 1)$ generated by

$$g(x) = (x - 1)(x - \omega)^3.$$ 

By Lemma 2.9, minimum Hamming distance $d_H = 3$ of $C$ can be derived and Lemma 2.4 implies that $d_p \geq 5$.

With arguments similar to the previous Proposition 3.2, there are no codewords of $C$ with Hamming weight $\omega_H = 4$ such that the 4 nonzero terms appear with consecutive coordinates.

We are left to show that there are no codewords of $C$ with Hamming weight $\omega_H = 3$ in the form

$$(\star, \star, 0_{s_1}, \star, 0_{s_2}),$$

where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_{s_1}, 0_{s_2}$ are all-zero vectors. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that

$$c(x) = 1 + a_1 x + a_2 x'^t.$$
Then \( c'(\omega) = c''(\omega) = 0 \) induces that \( t - 1 = kp \) for some positive integers \( k \leq l - 2 \), together with \( c(\omega) = 0 \), one can immediately get
\[
\begin{align*}
1 + a_1 \omega + a_2 \omega^{k+1} &= 0, \\
a_1 + a_2 \omega^k &= 0.
\end{align*}
\]
By solving the system, we have \( 1 = 0 \), which derive a contradiction.

For the case of \((r_1, r_2, r_3) = (0, 3, 1), (0, 1, 3)\), with similar to the previous Proposition 3.2, we can prove that these repeated-root cyclic codes are equivalent.

Therefore, \( \mathcal{C} \) is an MDS symbol pair code with minimum symbol-pair weight \( d_p = 6 \), when \((r_1, r_2, r_3) = (1, 0, 3), (0, 3, 1) \) and \((0, 1, 3)\).

\[\text{Proposition 3.4.} \quad \mathcal{C} \text{ is an MDS symbol pair code with } d_p = 6, \text{ if one of } (r_1, r_2, r_3) = (2, 0, 2) \text{ and } (0, 2, 2) \text{ is satisfied.}\]

\[\text{Proof.} \quad \text{When } (r_1, r_2, r_3) = (2, 0, 2), \text{ let } \mathcal{C} \text{ be a cyclic code in } \mathbb{F}_p[x]/(x^n - 1) \text{ generated by}
\]
\[g(x) = (x - 1)^2(x - \omega)^2.\]

By Lemma 2.9, minimum Hamming distance \( d_H = 3 \) of \( \mathcal{C} \) can be derived and Lemma 2.4 implies that \( d_p \geq 5 \).

With arguments similar to the previous Proposition 3.2, there are no codewords of \( \mathcal{C} \) with Hamming weight \( \omega_H = 4 \) such that the 4 nonzero terms appear with consecutive coordinates.

We are left to show that there are no codewords of \( \mathcal{C} \) with Hamming weight \( \omega_H = 3 \) in the form
\[(\ast, \ast, 0_{s_1}, \ast, 0_{s_2}),\]
where each \( \ast \) denotes an element in \( \mathbb{F}_p^* \) and \( 0_{s_1}, 0_{s_2} \) are all-zero vectors. Without loss of generality, suppose that the first coordinate of \( c(x) \) is 1. We denote that
\[c(x) = 1 + a_1 x + a_2 x'.\]

However, \( c'(1) = c'(\omega) = 0 \) can deduce that \( l \) is a divisor of \( t - 1 \), combine with \( c(1) = c(\omega) = 0 \), we have
\[
\begin{align*}
1 + a_1 + a_2 &= 0, \\
1 + a_1 \omega + a_2 \omega &= 0,
\end{align*}
\]
then we have \( \omega = 1 \), which is impossible, since \( \omega^l = 1 \) and \( l > 2 \).

When \((r_1, r_2, r_3) = (0, 2, 2)\), with similar to the previous Proposition 3.2, we can prove that these repeated-root cyclic codes are equivalent.

In fact, Lemma 2.7 is a special form of Proposition 3.3 and Proposition 3.4 for \( d_p = 6 \), where \( \omega \) is a \( \frac{l-1}{2} \)-th primitive element in \( \mathbb{F}_p \).

\[\text{Remark 3.5.} \quad \text{When } l \text{ even, factor } (x + 1) \text{ is contained in } x^l - 1; \text{ when } l \text{ odd, factor } (x + 1) \text{ is contained in } x^{2l} - 1.\]
From Lemma 2.6 to Lemma 2.8 and Proposition 3.2 to Proposition 3.4 we find all MDS symbol-pair codes containing these three factors \((x - 1), (x + 1)\) and \((x - \omega)\) with minimum symbol-pair distance \(d_p = 6\).

In what follows, we obtain more general generator polynomials for symbol-pair codes with length \(n = lp\) and minimum symbol-pair distance 5 or 6.

Let \(C_a\) be the cyclic codes in \(F_p[x] / (x^n - 1)\) and the generator polynomial of \(C_a\) is

\[
g_a(x) = (x - \omega t_1)^{r_1} (x - \omega t_2)^{r_2},
\]

where \(t_1 \geq t_2\), \(\text{ord}(\omega t_1) = m_1\), \(\text{ord}(\omega t_2) = m_2\), \(\text{lcm}[m_1, m_2] = l\), \(\text{gcd}(t_1 - t_2, l) = 1\), \(3 \leq r_1 + r_2 \leq 4\) and \(\omega\) is primitive element in \(F_p\).

**Corollary 3.6.** \(C_a\) is an MDS symbol-pair code, if \(r_1 \neq 0\) and \(r_2 \neq 0\).

**Proof.** There are three cases that need to be discussed, \((r_1, r_2) = (2, 1), (1, 3)\) and \((2, 2)\). When \((r_1, r_2) = (1, 2)\) and \((3, 1)\) is satisfied, it is similar to \((r_1, r_2) = (2, 1)\) and \((1, 3)\).

**Case I.** For the case of \((r_1, r_2) = (2, 1)\), if there exists a nonzero codeword with minimum Hamming weight \(d_H = 2\) in \(C_a\), without loss of generality, suppose that the first coordinate of \(c(x)\) is 1. We denote that

\[
c(x) = 1 + a_1 x^t,
\]

where \(a_1 \neq 0\) and \(t \neq 0\). It follows from \(c(\omega t_1) = c(\omega t_2) = 0\) that

\[
\begin{align*}
1 + a_1 \omega t_1 &= 0, \\
1 + a_1 \omega t_2 &= 0.
\end{align*}
\]

By solving the system, we have \(\omega t_1 t_2 = 1\). Together with \(\text{gcd}(t_1 - t_2, l) = 1\) and \(c'(\omega t_1) = 0\), one can immediately get \(lp\) is a divisor of \(t\), which contradicts with the code length \(lp\).

Thus, combined with Lemma 2.3, the minimum Hamming distance of \(C_a\) is \(d_H = 3\). By Lemma 2.4 we have \(C_a\) is an MDS \((lp, 5)\) symbol-pair code.

**Case II.** For the case of \((t_1, t_2) = (3, 1)\), we have the generator polynomial

\[
g_a(x) = (x - \omega t_1)^3 (x - \omega t_2).
\]

By the proof of **Case I**, since **Case II** is a subcode of **Case I**, we can draw the conclusion that the minimum Hamming weight of \(C_a\) is 3 in **Case II**, when \((t_1, t_2) = (3, 1)\).

If there is a codeword with Hamming weight 3 and symbol-pair weight 5. Then its certain cyclic shift must be the following form

\[
(\ast, \ast, 0_{t_1}, \ast, 0_{t_2}),
\]

where each \(\ast\) denotes an element in \(F_p^6\) and \(0_{t_1}, 0_{t_2}\) are all-zero vectors. Then we have a codeword polynomial

\[
c(x) = 1 + a_1 x + a_2 x^t.
\]

However, it follows from \(c'(\omega t_1) = c''(\omega t_1) = 0\) that

\[
\begin{align*}
a_1 + t a_2 \omega^{(t-1)t_1} &= 0, \\
t(t-1) a_2 \omega^{(t-2)t_1} &= 0.
\end{align*}
\]
By solving the system, we have $p \mid t - 1$. Then $c'(\omega^{t_1}) = c'(\omega^{t_2}) = 0$ indicates
\[
\begin{cases}
1 + a_1\omega^{t_1} + a_2\omega^{t_2} = 0, \\
a_1 + a_2\omega^{t(t-1)} = 0,
\end{cases}
\]
which means that $1 = 0$, a contradiction.

Therefore, there no exists a nonzero codeword with Hamming weight $\omega_H = 3$ and symbol-pair weight $\omega_p = 5$ and $C_a$ is an MDS $(lp, 6)_p$ symbol-pair code, when $(r_1, r_2) = (3, 1)$.

**Case III.** For the case of $(t_1, t_2) = (2, 2)$, similarly, we have the generator polynomial
\[g_a(x) = \left(x - \omega^{t_1}\right)^2 \left(x - \omega^{t_2}\right)^2,
\]
by the proof of **Case I**, we can draw the conclusion that the minimum Hamming weight of $C_a$ is 3.

Similar to **Case II**, there is no codeword with Hamming weight of $\omega_H = 4$ and symbol-pair weight of $\omega_p = 5$.

If there exists a codeword with Hamming weight $\omega_H = 3$ and symbol-pair weight $\omega_p = 5$, the codeword certain cyclic shift must have a form
\[\left(*, *, *, *, 0_k\right),
\]
where each $*$ denotes an element in $\mathbb{F}_p^*$ and $0_k$ is all-zero vector. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that
\[c(x) = 1 + a_1x + a_2x^t.
\]
However, $c'(\omega^{t_1}) = c'(\omega^{t_2}) = 0$ induces that
\[
\begin{cases}
a_1 + ta_2\omega^{t(t-1)}t_1 = 0, \\
a_1 + ta_2\omega^{t(t-1)}t_2 = 0.
\end{cases}
\]

By solving the system, we have $\omega^{t(t-1)}(t_1 - t_2) = 1$, since $t \not= kp$, otherwise $a_1 = 0$. Together with gcd $(t_1 - t_2, l) = 1$, one can immediately get $l \mid t - 1$ and $a_1 + ta_2 = 0$. Combined with $c'(\omega^{t_1}) = c'(\omega^{t_2}) = 0$, we have
\[
\begin{cases}
1 + a_1\omega^{t_1} + a_2\omega^{t_2} = 0, \\
1 + a_1\omega^{t_1} + a_2\omega^{t_2} = 0,
\end{cases}
\]
which implies $a_1 + a_2 = 0$. Thus, we have $p \mid t - 1$, which contradicts the code length $lp$.

Therefore, we prove that there no exists a nonzero codeword with Hamming weight $\omega_H = 3$ and symbol-pair weight $\omega_p = 5$ and $C_a$ is an MDS $(lp, 6)_p$ symbol-pair code, when $(r_1, r_2) = (2, 2)$ and gcd $(t_1 - t_2, l) = 1$.

In fact, similar to previous Proposition 1.2, **Case I** is equivalent to $g(x) = (x - 1)^2(x - \alpha)$ in Chen [9], **Case II** and **Case III** are equivalent to Proposition 3.3 and Proposition 3.2 respectively.

We use an example to illustrate that the repeated-root cyclic codes of the generator polynomials with the same forms in the above Corollary 3.6 are not all MDS symbol-pair codes.
Example 3.7. Let $C$ be a cyclic code in $\mathbb{F}_5[x]/\langle x^{20} - 1 \rangle$ and the generator polynomial of $C$ is
\[ g(x) = (x - 2)^2 (x - 3), \]
where $\omega = 3$ is a primitive element in $\mathbb{F}_5$ and $2 = 3^3$. Then we have the minimum Hamming distance $d_H = 2$ by a magma program. Therefore, $C$ is not an MDS symbol-pair code.

Similarly, when the generator polynomial of $C$ is one of
\[ g(x) = (x - 2)^3 (x - 3), \]
\[ g(x) = (x - 2)^2 (x - 3)^2, \]
$C$ is still not an MDS symbol-pair code, since minimum Hamming distance is $d_H = 2$.

3.2. MDS Symbol-Pair Codes of length $3p$

In this subsection, for $n = 3p$, we obtain all MDS symbol-pair codes of $d_p \leq 12$ from repeated-root cyclic codes and all AMDS symbol-pair codes of $d_p < 12$ from repeated-root cyclic codes. Furthermore, we discuss all minimum symbol-pair distance of the repeated-root cyclic codes with code length of $3p$, when $n - k < 10$. For preparation, we define the following notation.

Let $C_{r_1 r_2 r_3}$ be the cyclic code in $\mathbb{F}_p[x]/\langle x^n - 1 \rangle$ and the generator polynomial of $C_{r_1 r_2 r_3}$ is
\[ g_{r_1 r_2 r_3}(x) = (x - 1)^{r_1}(x - \omega)^{r_2}(x - \omega^2)^{r_3}. \]
where $\omega$ is a primitive $3$-th root of unity in $\mathbb{F}_p$ and $r_i \leq p - 1, i = 1, 2, 3$.

Proposition 3.8. Repeated-root cyclic codes $C_{r_1 r_2 r_3}$ are equivalent, where the exponents of the three factors of the generator polynomial can be exchanged with each other.

Proof. We first prove that such repeated-root cyclic codewords
\[ C = \langle (x - \omega)^{r_1} (x - \omega^{r_1 + 1})^{r_2} (x - \omega^{r_1 + 2})^{r_3} \rangle \]
are equivalent for $i = 0, 1, 2$.

Without loss of generality, suppose that
\[ C_{r_1 r_2 r_3} = \langle (x - 1)^{r_1} (x - \omega)^{r_2} (x - \omega^2)^{r_3} \rangle, \]
\[ C_{r_3 r_1 r_2} = \langle (x - \omega)^{r_1} (x - \omega^2)^{r_2} (x - 1)^{r_3} \rangle \]
and
\[ C_{r_2 r_3 r_1} = \langle (x - \omega^2)^{r_1} (x - 1)^{r_2} (x - \omega)^{r_3} \rangle. \]

We denote that $g_{r_1 r_2 r_3}(x)$, $g_{r_3 r_1 r_2}(x)$ and $g_{r_2 r_3 r_1}(x)$ represent the generator polynomials of $C_{r_1 r_2 r_3}$, $C_{r_3 r_1 r_2}$ and $C_{r_2 r_3 r_1}$, respectively.
Let \( y = \frac{x}{\omega^2}, z = \frac{x}{\omega^2} \). For the generating polynomial \( g_{r_1r_2r_3}(x) \) of \( C_{r_1r_2r_3} \), we can deduce the following results by deforming it.

\[
g_{r_1r_2r_3}(x) = (x - 1)^{r_1}(x - \omega)^{r_2}(x - \omega^2)^{r_3}
= \omega^{2(r_1 + r_2 + r_3)}(\frac{x}{\omega^2} - 1)^{r_1}(\frac{x}{\omega^2} - \omega)^{r_2}(\frac{x}{\omega^2} - \omega^2)^{r_3}
= \omega^{2(r_1 + r_2 + r_3)}(y - \omega)^{r_1}(y - \omega^2)^{r_2}(y - 1)^{r_3}
= \omega^{2(r_1 + r_2 + r_3)}g_{r_1r_2r_3}(y)
= \omega^{r_1 + r_2 + r_3}\left(z - \omega^2\right)^{r_1}\left(z - 1\right)^{r_2}(z - \omega)^{r_3}
= \omega^{r_1 + r_2 + r_3}g_{r_2r_1r_3}(z).
\]

Thus, repeated-root cyclic codes

\[
C = \left\langle (x - \omega)^{r_1}(x - \omega^2)^{r_2}(x - \omega^2)^{r_3}\right\rangle
\]

are equivalent for \( i = 0, 1, 2 \).

Next, since both \( \omega \) and \( \omega^2 \) are primitive 3-th root of unity in \( \mathbb{F}_p \), we have repeated-root cyclic code

\[
C_{r_1r_2r_3} = \left\langle (x - 1)^{r_1}(x - \omega)^{r_2}(x - \omega^2)^{r_3}\right\rangle
\]

and repeated-root cyclic code

\[
C_{r_1r_3r_2} = \left\langle (x - 1)^{r_1}(x - \omega^2)^{r_2}(x - \omega^2)^{r_3}\right\rangle,
\]

which are equivalent.

In conclusion, we prove all cases of this proposition, i.e. repeated-root cyclic codes \( C_{r_1r_2r_3}, C_{r_1r_3r_2}, C_{r_2r_1r_3}, C_{r_2r_3r_1}, C_{r_3r_1r_2} \) and \( C_{r_3r_2r_1} \) are equivalent to each other. \( \square \)

The above Proposition 3.8 shows that the exponential positions of the three factors \( x - 1, x - \omega \) and \( x - \omega^2 \) of the generator polynomial of \( C_{r_1r_2r_3} \) are equivalent. Without loss of generality, suppose that \( p - 1 \geq r_1 \geq r_2 \geq r_3 \geq 0 \) in the next part of this subsection. Then we have the following theorem.

**Theorem 3.9.** \( C_{r_1r_2r_3} \) is an MDS symbol-pair codes over \( \mathbb{F}_p \), if one of the following two conditions is true

1. \( r_1 \leq 5, 0 \leq r_2 - r_3 \leq 1 \) and \( r_1 = r_2 + r_3 \).
2. \( r_1 < 5, 0 \leq r_2 - r_3 \leq 1 \) and \( r_1 = r_2 + r_3 + 1 \).

Based on previous work and the results of this paper, all known MDS symbol-pair codes with \( n - k \leq 10 \) from repeated-root cyclic codes \( C_{r_1r_2r_3} \), which are listed in the following Table 2.

Similar to the previous MDS symbol-pair codes from repeated-root cyclic codes \( C_{r_1r_2r_3} \), for AMDS symbol-pair codes with \( n - k \leq 10 \), which are listed in the following Table 3.

Researchers have given some proofs of the Theorem 3.9 and the Theorem 4.1 in the previous paper also includes some proofs. Here we only need to prove that \( C_{221} \) is an MDS symbol-pair code.

</table>

These MDS symbol-pair codes are constructed by repeated-root cyclic codes.

**Proposition 3.10.** $C_{421}$ is an MDS $(3p, 9)_p$ symbol-pair code.

**Proof.** Since $C_{421} = \langle (x-1)^3(x-\omega)^2(x-\omega^2) \rangle$, for any codeword $c \in C$, we have

$$
c(1) = c(\omega) = c(\omega^2) = c'(1) = c'(\omega) = c''(1) = c''(\omega) = 0.
$$

By Lemma 2.9, $C_{421}$ is a $[3p, 3p-7, 5]$ cyclic code over $\mathbb{F}_p$. Since $C_{421}$ is a subcode of Lemma 2.5, we have $d_p \geq 8$.

To prove that $C_{421}$ is an MDS $(3p, 9)_p$ symbol-pair code, it suffices to verify that there does not exist codeword in $C_{421}$ with symbol-pair weight 8. Then we have three cases to discuss.

**Case I.** If there are codewords with Hamming weight $\omega_H = 5$ and symbol-pair weight $\omega_p = 8$, then its certain cyclic shift must be one of the following forms

$$(\ast, \ast, 0_{s_1}, \ast, \ast, 0_{s_2}, \ast, 0_{s_3})$$

or

$$(\ast, \ast, \ast, 0_{s_1}, \ast, 0_{s_2}, \ast, 0_{s_3}),$$

where each $\ast$ denotes an element in $\mathbb{F}_p^n$ and $0_{s_1}, 0_{s_2}, 0_{s_3}$ are all-zero vectors.

**Subcase 1.1** For the case of

$$(\ast, \ast, 0_{s_1}, \ast, \ast, 0_{s_2}, \ast, 0_{s_3}),$$

without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that

These AMDS symbol-pair codes are constructed by repeated-root cyclic codes.

$$c(x) = 1 + a_1x + a_2x^t + a_3x^{t+1} + a_4x^t.$$  

When $t \equiv 0 \pmod{3}$ and $l \equiv 0 \pmod{3}$, it follows from $c(1) = c(\omega) = c(\omega^2) = 0$ that

\[
\begin{cases}
1 + a_1 + a_2 + a_3 + a_4 = 0, \\
1 + a_1\omega + a_2 + a_3\omega + a_4 = 0, \\
1 + a_1\omega^2 + a_2 + a_3\omega^2 + a_4 = 0.
\end{cases}
\]

By solving the system, we have $a_1 = -a_3$. However, $c^t(1) = c^t(\omega) = 0$ induces that

\[
\begin{cases}
 a_1 + ta_2 + (t+1)a_3 + la_4 = 0, \\
a_1 + ta_2\omega^2 + (t+1)a_3 + la_4\omega^2 = 0.
\end{cases}
\]

Together with $a_1 = -a_3$, one can immediately get

\[
\begin{cases}
 ta_2 + ta_3 + la_4 = 0, \\
ta_2\omega^2 + ta_3 + la_4\omega^2 = 0,
\end{cases}
\]

and we can get $t(1 - \omega^2)a_3 = 0$, which is impossible, since $t \equiv 0 \pmod{3}$ and the code length is $3p$.

When $l \equiv i \pmod{3}$ and $t \equiv j \pmod{3}, i, j = 0, 1, 2$, values in all $i$ and $j$ of Subcase 1.1 are shown in the following Table 4.

</table>

Conditions [1], [2] and [3] represent $c(1) = c(\omega) = c(\omega^2) = 0$, $c'(1) = c'(\omega) = 0$ and $c(1) + c(\omega) + c(\omega^2) = 0$, respectively.

**Subcase 1.2** For the subcase of

$$(\ast, \ast, \ast, 0_{s_1}, \ast, 0_{s_2}, \ast, 0_{s_3})$$

without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that

$$c(x) = 1 + a_1x + a_2x^2 + a_3x^l + a_4x^t.$$  

Suppose that $l \equiv i (\mod 3)$ and $t \equiv j (\mod 3)$, $i, j = 0, 1, 2$, since $l$ and $t$ positionally equivalent, we need to discuss six situations here. Similar to **Subcase 1.1**, we summarize all $i$ and $j$ of **Subcase 1.2** in the following Table 5.

**Case II.** If there are codewords with Hamming weight $\omega_H = 6$ and symbol-pair weight $\omega_p = 8$, then its certain cyclic shift must be one of the following forms

$$(\ast, \ast, \ast, \ast, 0_{s_1}, \ast, 0_{s_2}),$$  

or

$$(\ast, \ast, \ast, 0_{s_1}, \ast, \ast, 0_{s_2}),$$  

where each $\ast$ denotes an element in $F_p^*$ and $0_{s_1}, 0_{s_2}, 0_{s_3}$ are all-zero vectors.
Conditions without loss of generality, suppose that the first coordinate of Subcase 2.

1. When \( t \equiv 0 \pmod{3} \), it can be derived from \( c(1) = c(\omega) = c(\omega^2) = 0 \) and \( c(1) + c(\omega) + c(\omega^2) = 0 \), respectively.

2. When \( t \equiv 1 \pmod{3} \), similar to \( t \equiv 0 \pmod{3} \), \( 2a_2 = 0 \) can be obtained from \( c(1) = c(\omega) = c(\omega^2) = 0 \) and \( c(1) + c(\omega) + c(\omega^2) = 0 \).

3. When \( t \equiv 2 \pmod{3} \), it follows from \( c(1) = c(\omega) = c(\omega^2) = 0 \) that

\[
\begin{align*}
1 + a_1 + a_2 + a_3 + a_4 + a_5 &= 0, \\
1 + a_1 \omega + a_2 \omega^2 + a_3 + a_4 \omega + a_5 \omega^2 &= 0, \\
1 + a_1 \omega^3 + a_2 \omega + a_3 + a_4 \omega^2 + a_5 \omega &= 0.
\end{align*}
\]

By solving the system, we have \( 1 + a_3 = 0, a_1 + a_4 = 0, a_2 + a_5 = 0 \). Then \( c'(1) = c'(\omega) = 0 \) indicates

\[
\begin{align*}
a_1 + 2a_2 + 3a_3 + 4a_4 + 5a_5 &= 0, \\
a_1 + 2a_2 \omega + 3a_3 \omega^2 + 4a_4 + 5a_5 \omega^2 &= 0,
\end{align*}
\]

which means that \( a_4 = a_3 \omega \) and \( a_5 = \frac{3a_3 \omega^2}{1 - \frac{3}{2}} \). (Since \( t \equiv 2 \pmod{3} \), then \( p \) is not a divisor of \( t - 2 \), otherwise \( t - 2 \geq 3p \).)

</tr>
</tbody>
</table>

Conditions \([1]\) and \([2]\) represent \( c(1) = c(\omega) = c(\omega^2) = 0 \) and \( c(1) + c(\omega) + c(\omega^2) = 0 \), respectively.
By \( c''(1) = 0 \), we have \( t = 3 + 2\omega \). Together with \( a_3\omega = a_4, \quad a_5 = \frac{3a_1\omega^2}{t - 2} \) and \( c''(1) = 0 \), then one can derive that
\[
6 + 24\omega + 3t(t - 1)\omega^2 = 0,
\]
we have
\[
2 + 8\omega + (3 + 2\omega)(2 + 2\omega)\omega^2 = 0,
\]
combining with \( \omega^2 = -1 - \omega \), we can obtain \( 3\omega^2 = 0 \), which is impossible.

**Subcase 2.2** For the subcase of
\[
(\ast, \ast, \ast, 0_{01}, \ast, \ast, 0_{b_2}),
\]
without loss of generality, suppose that the first coordinate of \( c(x) \) is 1. We denote that
\[
c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + 1.
\]
1. When \( t \equiv 0 \pmod{3} \), similar to \( t \equiv 0 \pmod{3} \) in **Subcase 2.1**, \( 2a_2 = 0 \) can be derived from \( c(1) = c(\omega) = c(\omega^2) = 0 \).
2. When \( t \equiv 1 \pmod{3} \), similar to \( t \equiv 2 \pmod{3} \) in **Subcase 2.1**, \( 1 + a_3 = 0, a_1 + a_4 = 0, \) and \( a_2 + a_5 = 0 \) can be obtained from \( c(1) = c(\omega) = c(\omega^2) = 0 \).

Then \( a_5 = a_4\omega \) and \( a_5 = \frac{3a_1\omega^2}{t - 1} \) can be derived from \( c'(1) = c'(\omega) = 0 \). \( c''(1) = 0 \) means \( t = -\omega \).

Finally, combined with \( c''(1) = 0 \), we have \( \omega^2 - \omega = 0 \), a contradiction.
3. When \( t \equiv 2 \pmod{3} \), similar to \( t \equiv 0 \pmod{3} \) in **Subcase 2.1**, \( 2a_2 = 0 \) can be derived from \( c(1) = c(\omega) = c(\omega^2) = 0 \).

**Subcase 2.3** For the subcase of
\[
(\ast, \ast, \ast, 0_{01}, \ast, \ast, 0_{b_2}),
\]
without loss of generality, suppose that the first coordinate of \( c(x) \) is 1. We denote that
\[
c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + 2.
\]
1. When \( t \equiv 0 \pmod{3} \), it follows from \( c(1) = c(\omega) = c(\omega^2) = 0 \) that
\[
\begin{align*}
1 + a_1 + a_2 + a_3 + a_4 + a_5 &= 0, \\
1 + a_1\omega + a_2\omega^2 + a_3 + a_4\omega + a_5\omega^2 &= 0, \\
1 + a_1\omega^2 + a_2\omega + a_3 + a_4\omega^2 + a_5\omega &= 0.
\end{align*}
\]

By solving the system, we have \( 1 + a_3 = 0, a_1 + a_4 = 0, a_2 + a_5 = 0 \). Then \( c'(1) = c'(\omega) = 0 \) indicates
\[
\begin{align*}
a_1 + 2a_2 + ta_3 + (t + 1)a_4 + (t + 2)a_5 &= 0, \\
a_1 + 2a_2\omega + ta_3\omega^2 + (t + 1)a_4 + (t + 2)a_5\omega &= 0,
\end{align*}
\]
which means that \( a_5 = a_4\omega = a_3\omega^2 \). Then \( c''(1) = 0 \) implies that
\[
2a_2 + t(t - 1)a_3 + t(t + 1)a_4 + (t + 1)(t + 2)a_5 = 0,
\]
which implies \( (3\omega^2 + \omega - 1 = 0) \). Since \( t \equiv 0 \pmod{3}, \omega = -\omega^2 - 1 \) and the code length \( 3p \), we have \( 2(\omega^2 - 1) = 0 \), a contradiction.
2. When \( t \equiv 1 \mod 3 \), with arguments similar to the previous \( t \equiv 0 \mod 3 \), by \( c(1) = c(\omega) = c(\omega^2) = 0 \) and \( \omega^2 = \omega \), we have \( a_4 = a_3 = 0 \). Together with \( c(1) = 0 \), \( \omega^2 = \omega = 0 \) can be derived, which is impossible.

3. When \( t \equiv 2 \mod 3 \), with arguments similar to the previous \( t \equiv 0 \mod 3 \), we can derive \( a_3 = \omega^3 \) from \( c(1) = c(\omega) = 0 \) and \( c(1) = c(\omega) = c(\omega^2) = 0 \). Together with \( c(1) = 0 \), we have \( t = p + 1 \). It follows from \( c(1) = c(\omega) = 0 \) that

\[
\begin{align*}
(t - 1)a_3 + (t + 1)a_4 + (t + 1)a_5 &= 0, \\
(t - 1)a_3 + (t + 1)a_4 + a_5 &= 0.
\end{align*}
\]

Combining \( t = p + 1 \), we have \( \omega^2 = 0 \), which contradicts that \( \omega \) is primitive 3-th root of unity in \( \mathbb{F}_p \).

**Case III.** If there are codewords in \( C \) with Hamming weight 7 and symbol-pair weight 8, then its certain cyclic shift must have the form

\[
(*,*,*,*,0_2,0_3),
\]

where each * denotes an element in \( \mathbb{F}_p \) and \( 0_3 \) is all-zero vector. Without loss of generality, suppose that the first coordinate of \( c(x) \) is 1. We denote

\[
c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6.
\]

This leads to \( \deg(c(x)) = 6 < 7 = \deg(g(x)) \).

As a result, \( C_{421} \) is an MDS \((3p,9)_p\) symbol-pair code.

In what follows, let’s determine the minimum symbol-pair distance for \( C_{r_1 r_2 r_3} \) in the previous paper by using the following propositions.

**Proposition 3.11.**

1. The minimum distance of \( C_{0r_20} \) is \( d_p = 4 \), when \( r_2 \geq 2 \).
2. The minimum distance of \( C_{210} \) is \( d_p = 5 \).
3. The minimum distance of \( C_{r_1 r_2 0} \) is \( d_p = 6 \), when \( r_1 + r_2 \geq 4 \) and \( r_1, r_2 \in \mathbb{F}_p^* \).
4. The minimum distance of \( C_{2r_2 r_3} \) is \( d_p = 6 \), when \( 2 \leq r_2 + r_3 \leq 4 \).

**Proof.** For \( C_{0r_20} = ((x - \omega)^2) \), Lemma 2.9 shows \( d_H(C_{0r_20}) = 2 \), then one can obtain \( d_p(C_{0r_20}) = 4 \) by Lemma 2.4.

Theorem 3.6 proves the minimum distance of \( C_{210} \) is \( d_p = 5 \).

Since \( C_{r_1 r_2 0} \) is a subcode of Theorem 3.6 and Lemma 2.9 means \( d_H(C_{r_1 r_2 0}) = 3 \). Then we have \( d_p(C_{r_1 r_2 0}) = 6 \).

Through Proposition 3.11, we can obtain all MDS and AMDS symbol-pair codes of length \( 3p \) with minimum symbol-pair distance of 4 to 6. Next, we look for MDS and AMDS symbol-pair codes with the minimum symbol pair distance \( d_p = 7 \).

**Proposition 3.12.** The minimum distance of \( C_{r_1 11} \) is \( d_p = 7 \), when \( 3 \leq r_1 \leq p - 1 \).
Proof. Reference [9] proved \( C_{311} \) is an MDS symbol-pair code with the minimum symbol-pair distance \( d_p = 7 \).

Since \( C_{r_{111}} \) is a subcode of \( C_{311} \), we have \( d_p(C_{r_{111}}) \geq 7 \). Then the minimum symbol-pair distance \( d_p(C_{r_{111}}) = 7 \) can be obtained by \( \omega_p(c(x)) = 7 \), where \( c(x) = 1 - x - x^3 + x^{3p+1} \) is a codeword of \( C_{r_{111}} \).

From this proposition, we can deduce that \( C_{r_{111}} \) is an AMDS symbol-pair code with the minimum symbol-pair distance 7 if and only if \( r_1 = 4 \). Through the following proposition, we find the AMDS symbol-pair codes with the minimum symbol-pair distance 8.

**Proposition 3.13.** The minimum distance of \( C_{3p_2^r} \) is \( d_p = 8 \), when \( 3 \leq r_2 + r_3 \leq 6 \).

Proof. Similar to the previous Proposition 3.12, Reference [9] proved that \( C_{321} \) is an MDS \((3p, 8)_p\) symbol-pair code. Since \( 3 \leq r_2 + r_3 \leq 6 \), we have \( C_{3p_2^r} \) is subcode of \( C_{321} \) and \( d_p(C_{3p_2^r}) \geq 8 \).

By Lemma 2.9, we can deduce that the minimum Hamming distance of \( C_{3p_2^r} \) is 4, which implies \( d_p(C_{3p_2^r}) \leq 8 \).

Therefore, the minimum distance of \( C_{3p_2^r} \) is \( d_p = 8 \), when \( 3 \leq r_2 + r_3 \leq 6 \). \( \square \)

Proposition 3.13 indicates that \( C_{3p_2^r} \) is an AMDS symbol-pair code with \( d_p = 8 \), if \( r_2, r_3 \neq 0 \) and \( r_2 + r_3 = 4 \). Proposition 3.10 shows that \( C_{321} \) is an MDS symbol-pair code with minimum symbol-pair distance 9. In what follows, we will give all AMDS symbol-pair codes with minimum symbol-pair distance 9.

**Proposition 3.14.** The minimum distance of \( C_{r_{21}} \) is \( d_p = 9 \), when \( 4 \leq r_1 \leq p - 1 \) and \( 2 \leq r_2 \leq p - 1 \).

Proof. With arguments similar as the proof of Proposition 3.12 since \( C_{321} \) is an MDS symbol-pair code with the minimum symbol-pair distance 9, we can deduce that the minimum symbol-pair distance of \( C_{r_{21}} \) is \( d_p(C_{r_{21}}) \geq 9 \). Next, we will prove that there are symbol-pair codewords with symbol-pair weight \( d_p = 9 \) in \( C_{r_{21}} \).

For the codeword

\[
\omega_p(c(x)) = (x - 1)^p(x - \omega)(x - \omega^2) = x^{2p+1} - \omega^2 x^{2p} + \omega^3 x^{p+1} - \omega x^p + \omega x - 1,
\]

it is easy to verify that \( c(x) \) is a codeword polynomial of \( C_{r_{21}} \) with the symbol-pair weight \( \omega_p(c(x)) = 9 \). Thus, we have \( d_p(C_{r_{21}}) = 9 \). \( \square \)

From Proposition 3.14 we can determine that \( C_{r_{21}} \) is an AMDS symbol-pair code with \( d_p = 9 \), if and only if one of \( r_1 = 5, r_2 = 2 \) and \( r_1 = 4, r_2 = 3 \) is satisfied. The following proposition will show that symbol-pair codes with minimum symbol-pair distance \( d_p = 10 \).

**Proposition 3.15.** The minimum distance of \( C_{r_{21}3} \) is \( d_p = 10 \), when \( r_1, r_2 \) and \( r_3 \) meet any of the following two conditions

1. \( 4 \leq r_1 \leq p - 1 \) and \( r_2 = r_3 = 2 \),
2. \( r_1 = 4 \) and \( 4 \leq r_2 + r_3 \leq 8 \).
Proof. For $4 \leq r_1 \leq p - 1$ and $r_2 = r_3 = 2$, with arguments similar as the proof of Proposition 3.12, reference [13] proved $C_{422}$ is an MDS symbol-pair code with $d_p = 10$. Since $C_{11223}$ is a subcode of $C_{422}$, we have $d_p(C_{11223}) \geq 10$.

Note that the codeword polynomial
\[ c(x) = 1 - x^2 - 2x^{p+1} + x^{p+2} - x^{2p} - 2x^{2p+1} \]
is a codeword of $C_{1122}$ and $\omega_p(c(x)) = 10$. Therefore, we derive the minimum symbol-pair distance of $C_{1122}$ is 10.

For $r_1 = 4$ and $4 \leq r_2 + r_3 \leq 8$, since $C_{4223}$ is a subcode of $C_{422}$, we have $d_p(C_{4223}) \geq 10$.

However, Lemma 2.9 shows that $d_H(C_{4223}) = 5$, which implies that $d_p(C_{4223}) \leq 10$. Thus, we can deduce $d_p(C_{4223}) = 10$. \hfill \Box

From Proposition 3.12 to Proposition 3.15, our proof contains all minimum symbol-pair distances of repeated-root cyclic codes $C_{r_1r_2r_3}$, where the degree of the generator polynomials of $C_{r_1r_2r_3}$ is less than 11. Under the above constraints, we can easily deduce that there is no repeated-root cyclic code with a minimum symbol-pair distance $d_p = 11$. We have the following corollary.

Corollary 3.16. The repeated-root cyclic code $C_{r_1r_2r_3}$ must not be the MDS and the AMDS symbol-pair code with a minimum symbol-pair distance $d_p = 11$.

Proposition 3.15 shows that the condition does not satisfy Theorem 3.9 when $r \geq 5$ and $r_1 = r_2 + r_3 + 1$. Next, we use an example to illustrate that the conditions of Theorem 3.9 are also no longer applicable, when $r > 5$ and $r_1 = r_2 + r_3$.

Example 3.17. Let $C$ be a repeated-root cyclic code in $\mathbb{F}_7[x]/\langle x^7 - 1 \rangle$ and the generator polynomial of $C$ is
\[ g(x) = (x - 1)^6(x - 2)^3(x - 4)^3, \]
where $\omega = 2$ is a 3-th primitive element in $\mathbb{F}_7$ and $2^3 = 4$.

Then we have the minimum Hamming distance $d_H = 7$ by a magma program. Reference [13] shows the symbol-pair distance $d_p \geq 12$. The magma program also shows that both vectors
\[ a = [0 0 1 0 0 0 0 0 6 6 3 3 3 4 4 4 5 1 1] \]
and
\[ b = [0 0 0 0 0 1 0 0 1 1 5 4 4 3 3 3 6 6] \]
are in $C$. We add the two vectors $a + b$ to get the new vector $c$,
\[ c = [0 0 1 0 0 0 1 0 0 0 4 1 0 1 1 0 1 4 0 0], \]
which is also in $C$. We can easily deduce $\omega_p(c) = 13$. Therefore, $C$ is not an MDS symbol-pair code.

3.3. AMDS Symbol-Pair Codes

In this subsection, for length $lp$ and $4p$, we propose two new classes of AMDS symbol-pair codes. For preparation, we define the following notation.

Let $C_1$ and $C_2$ be the cyclic codes in $\mathbb{F}_p[x]/\langle x^4 - 1 \rangle$. The generator polynomial of $C_1$ is
\[ g_1(x) = (x - 1)^7(x + 1)(x - \omega), \]
where \( \omega \) is a primitive \( l \)-th root of unity in \( \mathbb{F}_p \). The generator polynomial of \( C_2 \) is

\[
g_2(x) = (x - 1)^3 (x + 1)^2 (x^2 + 1),
\]

where \( \omega \) is a primitive 4-th root of unity in \( \mathbb{F}_p \), when \( p \equiv 1 \pmod{4} \), and \( \omega \) is a primitive 4-th root of unity in \( \mathbb{F}_p \setminus \mathbb{F}_p \), when \( p \equiv 3 \pmod{4} \).

Now we present a class of AMDS symbol-pair codes with \( n = lp \) and minimum symbol-pair distance 7.

**Theorem 3.18.** \( C_1 \) is an AMDS \((lp, 7)_p\) symbol-pair code, if \( l \) odd and \( l \geq 3 \).

**Proof.** \( C_1 \) is the cyclic code in \( \mathbb{F}_p[x] / (x^n - 1) \) generated by

\[
g_1(x) = (x - 1)^4 (x - \omega) (x - \omega^2).
\]

By Lemma 2.9 one can derive that \( C_1 \) is an \([lp, lp - 6, 4]\) repeated-root cyclic codes code over \( \mathbb{F}_p \). Lemma 2.4 yields that \( d_p \geq 6 \), since \( C_1 \) is not an MDS cyclic code. To prove that \( C_1 \) is an AMDS symbol-pair code with the minimum symbol-pair distance 7, it is sufficient to verify that there is no a codeword in \( C_1 \) with the symbol-pair weight 6.

If there are codewords in \( C_1 \) with Hamming weight 5 and symbol-pair weight 6, then its certain cyclic shift must have the form

\[
(*, *, *, *, *, 0_s),
\]

where each \(*\) denotes an element in \( \mathbb{F}_p^* \) and \( 0_s \) is all-zero vector. Without loss of generality, suppose that the first coordinate of \( c(x) \) is 1. We denote that

\[
c(x) = 1 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4,
\]

This leads to \( \deg(c(x)) = 4 < 6 = \deg(g(x)) \).

If \( c \in C \) has the symbol-pair weight 6 with the Hamming weight 4, then its certain cyclic shift must have the forms

\[
(*, *, *, 0_{s1}, *, 0_{s2})
\]

or

\[
(*, *, 0_{s1}, *, *, 0_{s2}),
\]

where each \(*\) denotes an element in \( \mathbb{F}_p^* \) and \( 0_{s1}, 0_{s2} \) are all-zero vectors.

**Case I.** For the case of

\[
(*, *, *, 0_{s1}, *, 0_{s2}),
\]

without loss of generality, we denote a codeword polynomial

\[
c(x) = 1 + a_1 x + a_2 x^2 + a_3 x^3.
\]

It follows from \( c'(1) = c''(1) = 0 \) that

\[
\begin{align*}
a_1 + 2a_2 + ta_3 &= 0, \\
2a_2 + t(t - 1)a_3 &= 0.
\end{align*}
\]
By solving the system, we have $t(t - 2)a_3 = a_1$. Then one induces that $t - 2 \neq kp, k < l$ and $t \neq kp, k < l$. By $c''(1) = 0$, we can conclude that $t \neq kp, k < l$ and $t - 1 \neq kp, k < l$. However, $c''(1) = 0$ implies 
\[ t(t - 1)(t - 2)a_3 = 0, \]
then one can be checked that 
\[ t(t - 1)(t - 2) = kp, \]
which contradicts $t \neq kp, t - 1 \neq kp$ and $t - 2 \neq kp$.

**Case II.** For the case of 
\[ (*, *, 0_{11}, *, *, 0_{l_2}), \]
without loss of generality, we denote 
\[ c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^{l+1}. \]
It follows from $c(1) = c'(1) = 0$ that 
\[ \begin{cases} 
1 + a_1 + a_2 + a_3 = 0, \\
1 + a_2 + (t + 1)a_3 = 0,
\end{cases} \]
one can derive that 
\[ (t - 1)a_2 + ta_3 - 1 = 0. \]
By $c''(1) = 0$, we have 
\[ t(t - 1)a_2 + t(t + 1)a_3 = 0. \]
This leads to $t(a_3 + 1) = 0$. Therefore, we have $t = kp, 0 < k < l$ or $a_3 = -1$.

If $t = kp, 0 < k < l$, then 
\[ \begin{cases} 
1 + a_1 + a_2 + a_3 = 0, \\
a_1 + a_3 = 0,
\end{cases} \]
This indicates $a_1 = -a_3$ and $a_2 = -1$. Combined with $c(\omega) = c(\omega^2) = 0$, we have 
\[ \begin{cases} 
a_1\omega(\omega^l - 1) = 1 - \omega^l, \\
a_1\omega^2(\omega^{2l} - 1) = 1 - \omega^{2l}.
\end{cases} \]
By solving the system, we have $\omega^{2l} = 1$, which contradicts $l$ odd.

If $a_3 = -1$, by $c(1) = 0$, we can obtain that $a_1 = -a_2$. Combined with $c(\omega) = c(\omega^2) = 0$, we have 
\[ \begin{cases} 
a_1\omega(\omega^{l-1} - 1) = 1 - \omega^{l+1}, \\
\omega^2(\omega^{2l-2} - 1) = 1 - \omega^{2l+2}.
\end{cases} \]
Since $\omega$ is a primitive $l$-th root of unity, then 
\[ \omega(\omega^{l-1} + 1)(1 - \omega^{l+1}) = 1 - \omega^{2l+2}. \]
This implies that $\omega^l = 1$. Thus, $a_1 = -1, a_2 = 1$. By 
\[ t(t - 1)a_2 + t(t + 1)a_3 = 0, \]
we have $2t = kp$, which contradicts $\omega^l = 1$. 

21
In order to prove that $C_1$ is an AMDS symbol-pair code, we need to find a codeword with the symbol-pair weight 7. Since

$$c(x) = (x^p - 1)(x^{p-1} - 1) = x^{2p-1} - x^p - x^{p-1} + 1$$

is a codeword of $C_1$ and $\omega_p(c(x)) = 7$, $C_1$ is an AMDS $(1p, 7)_p$ symbol-pair code.

In what follows, we construct a class of AMDS symbol-pair codes with $n = 4p$ and minimum symbol-pair distance 8.

**Theorem 3.19.** $C_2$ is an AMDS $(4p, 8)_p$ symbol-pair code.

**Proof.** Since $C_2$ is the cyclic code in $\mathbb{F}_p[x]/\langle x^n - 1 \rangle$ generated by

$$g_2(x) = (x - 1)^3(x + 1)^2(x^2 + 1).$$

For any codeword $c \in C$, we have

$$c(1) = c(-1) = c(\omega) = c(-\omega) = c'(1) = c''(1) = 0,$$

where $\omega$ is a primitive 4-th root of unity in $\mathbb{F}_{p^2} \setminus \mathbb{F}_p$ or $\mathbb{F}_p$.

By Lemma 2.3, $C_2$ is an $[4p, 4p-7, 4]$ cyclic code over $\mathbb{F}_p$. Since $C_2$ is not an MDS cyclic code, Lemma 2.4 yields that $d_p \geq 6$.

When $p \equiv 3 \pmod{4}$, since $C_2$ is a subcode of Lemma 2.3 and it is shown in the proof of Lemma 2.5 that there does not exist a codeword in $C_2$ with symbol-pair weight 6 and 5.

When $p \equiv 1 \pmod{4}$, we are left to show that there are no codewords of $C_2$ with symbol-pair weight 6 and Hamming weight 4 or 5.

**Case I.** Assume that $c(x)$ has the Hamming weight 5 and the symbol-pair weight 6. Then its certain cyclic shift must have the form

$$(\star, \star, \star, \star, 0_x),$$

where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_x$ is all-zero vector. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. Then

$$c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^4$$

is a codeword of $C_2$. However, this leads to $\deg(c(x)) = 4 < 7 = \deg(g(x))$.

**Case II.** Assume that $c(x)$ has the Hamming weight 4 and the symbol-pair weight 6. Then its certain cyclic shift must have one of the forms

$$(\star, \star, \star, 0_x_1, 0_x_2)$$

or

$$(\star, \star, 0_x_1, \star, 0_x_2),$$

where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_x_1, 0_x_2$ are all-zero vectors. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1.
1. For the subcase of 
\((\ast, \ast, \ast, 0_{r_1}, \ast, 0_{r_2})\), 
without loss of generality, we denote 
\[ c(x) = 1 + a_1 x + a_2 x^2 + a_3 x^t, \]
where \(a_i \in \mathbb{F}_p^*\) for any \(0 \leq i \leq 3\) and \(4 \leq t \leq 4p - 2\).
When \(t\) is even, since \(c(1) = c(-1) = 0\), it can be verified that 
\[
\begin{align*}
1 + a_1 + a_2 + a_3 &= 0, \\
1 - a_1 + a_2 + a_3 &= 0.
\end{align*}
\]
Then one can derive that \(2a_1 = 0\), this contradicts \(a_1 \in \mathbb{F}_p^*\).
When \(t\) is odd, it follows from \(c'(1) = c'(-1) = 0\) that 
\[
\begin{align*}
a_1 + 2a_2 + ta_3 &= 0, \\
a_1 - 2a_2 + ta_3 &= 0,
\end{align*}
\]
which implies \(4a_1 = 0\). This contradicts with \(a_1 \in \mathbb{F}_p^*\).

2. For the subcase of 
\((\ast, \ast, 0_{r_1}, \ast, \ast, 0_{r_2})\), 
Without loss of generality, denote 
\[ c(x) = 1 + a_1 x + a_2 x^t + a_3 x^{t+1}, \]
where \(a_i \in \mathbb{F}_p^*\) for any \(0 \leq i \leq 3\) and \(4 \leq t \leq 4p - 3\).
When \(t\) is odd, it follows from \(c'(1) = c'(-1) = 0\) that 
\[
\begin{align*}
a_1 + ta_2 + (t+1)a_3 &= 0, \\
a_1 + ta_2 - (t+1)a_3 &= 0,
\end{align*}
\]
which implies \(t = 2p - 1\). However, \(c''(1) = 0\) induces that 
\[ t(t - 1)a_2 - t(t + 1)a_3 = 0. \]
Together with \(t = 2p - 1\), one can immediately get \((2p - 1)(2p - 2) = 0\). This is impossible, since \(p\) is an odd prime.
When \(t\) is even, it follows from \(c'(1) = c'(-1) = 0\) that 
\[
\begin{align*}
a_1 + ta_2 + (t+1)a_3 &= 0, \\
a_1 - ta_2 + (t+1)a_3 &= 0,
\end{align*}
\]
which implies \(t = 2p\).
Since \(c(1) = c(-1) = 0\), it can be verified that 
\[
\begin{align*}
1 + a_1 + a_2 + a_3 &= 0, \\
1 - a_1 + a_2 - a_3 &= 0.
\end{align*}
\]
Then one can derive that \(a_1 + a_3 = 0\). However, \(c(\omega) = c(-\omega) = 0\) induces that 
\[
\begin{align*}
1 + a_1 \omega + a_2 \omega^t + a_3 \omega^{t+1} &= 0, \\
1 - a_1 \omega + a_2 \omega^t - a_3 \omega^{t+1} &= 0,
\end{align*}
\]
which implies \(a_1 \omega + a_3 \omega^{t+1} = 0\). By substituting \(t = 2p\) and \(a_1 + a_3 = 0\), one can derive that \(a_1 = a_3 = 0\), which is contradicts \(a_i \in \mathbb{F}_p^*\).
Through the above proof, we conclude that there is no codeword with symbol-pair weight of 6 in $C_2$. Therefore, to prove that $C_2$ is an AMDS symbol-pair code with minimum symbol-pair distance 8, it is sufficient to verify that there does not exist a codeword in $C_2$ with symbol-pair weight 7. We have three cases to discuss.

**Case III.** If there is a codeword in $C_2$ with Hamming weight 6 and symbol-pair weight 7, then its certain cyclic shift must have the form

\[(\star, \star, \star, \star, \star, 0_s),\]

where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_s$ is all-zero vector. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1. We denote that

\[c(x) = 1 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5,\]

this leads to $\text{deg}(c(x)) = 5 < 7 = \text{deg}(g(x))$.

Therefore, it shows that there does not exist a codeword in $C_2$ with Hamming weight 6 and symbol-pair weight 7.

**Case IV.** Assume that $c(x)$ has the Hamming weight 5 and the symbol-pair weight 7. Then its certain cyclic shift must have one of the forms

\[(\star, \star, \star, 0_{s_1}, \star, 0_{s_2})\]

or

\[(\star, \star, \star, \star, 0_{s_1}, 0_{s_2}),\]

where each $\star$ denotes an element in $\mathbb{F}_p^*$ and $0_{s_1}, 0_{s_2}$ are all-zero vectors. Without loss of generality, suppose that the first coordinate of $c(x)$ is 1.

1. For the subcase of

\[(\star, \star, \star, 0_{s_1}, \star, 0_{s_2}),\]

without loss of generality, we denote

\[c(x) = 1 + a_1x + a_2x^2 + a_3x^l + a_4x^{l+1},\]

where $a_i \in \mathbb{F}_p^*$ for any $1 \leq i \leq 4$ and $5 \leq l \leq 4p - 3$.

When $l$ even, it can be verified that

\[
\begin{align*}
   a_1 + 2a_2 + la_3 + (l+1)a_4 &= 0, \\
   a_1 - 2a_2 - la_3 + (l+1)a_4 &= 0,
\end{align*}
\]

since $c'(1) = c'(-1) = 0$. Then one can derive that $l = 2p$.

However, it follows from $c''(1) = 0$ that

\[2a_2 + l(l-1)a_3 + l(l+1)a_4 = 0.\]

By substituting $l = 2p$, one can obtain that $2a_1 = 0$, which contradicts $a_1 \neq 0$. 

24
When $l$ odd, it can be verified that
\[
\begin{aligned}
1 + a_1 + a_2 + a_3 + a_4 &= 0, \\
1 - a_1 + a_2 - a_3 + a_4 &= 0, \\
a_1 + 2a_2 + la_3 + (l+1)a_4 &= 0, \\
a_1 - 2a_2 + la_3 - (l+1)a_4 &= 0,
\end{aligned}
\]
since $c(1) = c(-1) = c'(1) = c'(-1) = 0$. By solving the system, one can derive that $l = 2p + 1$. This implies that
\[
\begin{aligned}
a_2 + a_4 &= -2, \\
2a_2 + (l+1)a_4 &= 0,
\end{aligned}
\]
then one can derive that $2 = 0$, a contradiction.

2. For the subcase of
\[
(\ast, \ast, \ast, 0, 0, 0, 0, 0),
\]
without loss of generality, we denote
\[
c(x) = 1 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4,
\]
where $a_i \in \mathbb{F}_p^*$ for any $0 \leq i \leq 4$ and $5 \leq l \leq 4p - 2$.

When $l$ is odd, with $5 \leq l \leq 4p - 2$ and $a_i \in \mathbb{F}_p^*$ for any $1 \leq i \leq 4$. The fact $c(1) = c(-1) = 0$ induces that
\[
\begin{aligned}
1 + a_1 + a_2 + a_3 + a_4 &= 0, \\
1 - a_1 + a_2 - a_3 - a_4 &= 0.
\end{aligned}
\]
This implies that $a_2 = -1$. However, it follows from $c(\omega) = c(-\omega) = 0$ that
\[
\begin{aligned}
1 + a_1 \omega - a_2 - a_3 \omega + a_4 (\omega) &= 0, \\
1 - a_1 \omega - a_2 + a_3 \omega - a_4 (\omega) &= 0.
\end{aligned}
\]
This leads to $a_2 = 1$, which contradicts $a_2 = -1$.

When $l$ is even, with $6 \leq l \leq 4p - 2$ and $a_i \in \mathbb{F}_p^*$ for any $1 \leq i \leq 4$. The fact $c(1) = c(-1) = 0$ induces that
\[
\begin{aligned}
1 + a_1 + a_2 + a_3 + a_4 &= 0, \\
1 - a_1 + a_2 - a_3 + a_4 &= 0.
\end{aligned}
\]
This implies that $a_1 + a_3 = 0$. However, It follows from $c(\omega) = c(-\omega) = 0$ that
\[
\begin{aligned}
1 + a_1 \omega - a_2 - a_3 \omega + a_4 (\omega) &= 0, \\
1 - a_1 \omega - a_2 + a_3 \omega + a_4 (\omega) &= 0.
\end{aligned}
\]
This leads to $a_1 - a_3 = 0$. Therefore, by using $a_1 + a_3 = 0$, one can immediately obtain that $a_1 = a_3 = 0$, which contradicts $a_i \in \mathbb{F}_p^*$ for any $1 \leq i \leq 4$.

Therefore, there does not exist codeword in $C_2$ with Hamming weight 5 and symbol-pair weight 7.
Case V. Assume that \( c(x) \) has Hamming weight 4 and symbol-pair weight 7. Then its certain cyclic shift must have the form

\[
c = (*, *, 0_{s1}, *, 0_{s2}, *, 0_{s3}),
\]

where each \(*\) denotes an element in \( \mathbb{F}_p^* \) and \( 0_{s1}, 0_{s2}, 0_{s3} \) are all-zero vectors. Without loss of generality, suppose that the first coordinate of \( c(x) \) is 1,

\[
c(x) = 1 + a_1x + a_2x^u + a_3x^v,
\]

where \( 3 \leq u, v \leq 4p - 2 \), \( |u - v| > 1 \).

- If both \( u \) and \( v \) are even, then we have

\[
\begin{align*}
1 + a_1 + a_2 + a_3 &= 0, \\
1 - a_1 + a_2 + a_3 &= 0,
\end{align*}
\]

since \( c(1) = c(-1) = 0 \). It follows that \( 2a_1 = 0 \), which contradicts \( a_1 \neq 0 \).

- If both \( u \) and \( v \) are odd, it follows from \( c(1) = c(-1) = 0 \) that

\[
\begin{align*}
1 + a_1 + a_2 + a_3 &= 0, \\
1 - a_1 - a_2 - a_3 &= 0,
\end{align*}
\]

which indicates \( 2 = 0 \). Without loss of generality, let \( u \) is odd and \( v \) is even.

- When \( v \equiv 0 \pmod{4} \), since \( c'(1) = c'(-1) = 0 \) then

\[
\begin{align*}
a_1 + ua_2 + va_3 &= 0, \\
a_1 + ua_2 - va_3 &= 0,
\end{align*}
\]

which implies that \( 4p \) is a divisor of \( v \). This contradicts with the code length \( n = 4p \).

- When \( v \equiv 2 \pmod{4} \), since \( c'(1) = c'(-1) = 0 \), we have

\[
\begin{align*}
a_1 + ua_2 + va_3 &= 0, \\
a_1 + ua_2 - va_3 &= 0.
\end{align*}
\]

this means that \( 2p \) is a divisor of \( v \). Together with

\[
u(u - 1)a_2 + v(v - 1)a_3 = 0,
\]

we have \( u(u - 1)a_2 = 0 \).

If \( u = kp \) for some positive integers \( k \), we can obtain \( a_1 = 0 \) by \( c'(1) = c'(-1) = 0 \), which is impossible.

If \( u - 1 = kp \) for some positive integers \( k \), \( k = 2 \) can be derived from \( u \) odd and the code length \( 4p \). Hence, we have \( u = 2p + 1, v = 2p \). However, this contradicts with \( |u - v| > 1 \).

Therefore, there does not exist codeword in \( C_2 \) with Hamming weight 4 and symbol-pair weight 7.

As a result, \( C_2 \) is an AMDS \( (4p, 8)_p \) symbol-pair code. \( \square \)
4. Conclusion

In this paper, employing repeated-root cyclic codes, three new classes of MDS symbol-pair codes over $\mathbb{F}_p$ with length $lp$ and $3p$ are provided. Theorem 3.1 and Corollary 3.6 give some more general generator polynomials about MDS $(lp,5)_p$ and $(lp,6)_p$ symbol-pair codes. For length $3p$, Theorem 3.9 provides all MDS symbol-pair codes with $d_p \leq 12$ and also provides all AMDS symbol-pair codes with $d_p < 12$. This paper is also given two new classes of AMDS symbol-pair codes over $\mathbb{F}_p$ with length $lp$ and $4p$. Theorem 3.18 obtains a class of AMDS $(lp,7)_p$ symbol-pair codes and Theorem 3.19 presents a class of AMDS $(4p,8)_p$ symbol-pair codes.
