Energetic coherence is a valuable resource for various operations, including precise measurement of time and acceleration of quantum manipulations. Recently, it has been shown that the theory of energetic coherence, called the resource theory of asymmetry, has a thermodynamic structure, as do entanglement theory and quantum thermodynamics. In the so-called i.i.d. regime, where identical copies of a state are converted into identical copies of another state, the convertibility is entirely determined by the amount of energetic coherence measured by the quantum Fisher information (QFI). This fact means that QFI takes the place of entropy in thermodynamics and entanglement entropy in entanglement theory. So far, such a correspondence between energetic coherence and entropy is known only in the i.i.d. regime. In entanglement theory and quantum thermodynamics in the non-i.i.d. regime, entropy-related quantities based on the information-spectrum method reveal a non-equilibrium thermodynamics structure. Still, it has been an open question whether a similar structure exists for energetic coherence. In this Letter, we solve this problem by constructing an information-spectrum method applicable to the quantum Fisher information content. As a result, we establish a general theory of the pure-state convertibility in the non-i.i.d. regime of the resource theory of asymmetry. The given theory reveals a non-equilibrium thermodynamic structure of energetic coherence in the non-i.i.d. regime, based on QFI rather than entropy.

Introduction.— In quantum mechanics, different states can be superposed and exist simultaneously. This property is a fundamental concept in quantum physics and an origin of quantum resources for various physical operations. Among such resources, energetic coherence is as vital as entanglement. This resource is mandatory for accurately measuring time and creating accurate clocks [1–6], accelerating quantum operations [7], and measuring physical quantities noncommutative with conserved quantities [8–12]. Recently, it has been shown that energetic coherence also plays important roles for gate implementation in quantum computation [13–16], quantum error correction [16–20] and black hole physics [16].

When considering energetic coherence as a resource, it is essential to clarify the limitations on distillation and dilution of the coherence. Here, distillation is the operation of gathering a large number of “weak” resource states to create a small number of “strong” resource states [21], and dilution is the opposite. Knowledge of the limitations on distillation and dilution is essential for two reasons. First, coherence is very fragile and easily damaged by noise. Distillation and dilution can counter this destruction since they help regain weakened coherence. Second, understanding the limits of distillation and dilution provides a fundamental understanding of whether we can assemble multiple inaccurate clocks to create an accurate clock [5]. In particular, it is interesting whether a small number of physical quantities can characterize such limitations. If possible, it would imply the existence of “thermodynamic potentials” for energetic coherence and a thermodynamics theory in the field of precise measurements of time.

Because of the above importance, distillation and dilution of energetic coherence have been studied in the resource theory of asymmetry (RTA), a resource theory that analyzes symmetry and conservation laws [12, 14–16, 22–27]. RTA analysis for the independent and identically distributed (i.i.d.) case [26] has been very successful, clarifying that a structure quite similar to entanglement theory and quantum thermodynamics exists for energetic coherence. In pure-state entanglement theory and quantum thermodynamics, the entropy (entanglement entropy in entanglement theory and von Neumann entropy in quantum thermodynamics) completely determines whether distillation and dilution are possible in the i.i.d. regime. In the same way, in the i.i.d. regime of RTA, the convertibility of pure states is completely characterized by the quantum Fisher information (QFI) content. In other words, QFI is in the position of entropy in the second law of thermodynamics.

The energetic coherence in RTA has the same structure as entropy in thermodynamics, at least in the i.i.d. regime. Thus, a natural question arises. Is this correspondence valid beyond the i.i.d. regime? This question is crucial in two respects. First, in realistic settings, the states do not satisfy the i.i.d. assumption. Therefore, to know the realistic limits of distillation and dilution, it is essential to explore the non-i.i.d. regime, where the states have general and complex correlations. Second, in the non-i.i.d. regime, it is known that the entanglement theory [28, 29] and quantum thermodynamics [30, 31] have the structures corresponding to Lieb-Yngvason’s non-equilibrium thermodynamics [32, 33]. It is a fundamental physical question to clarify whether the same
structure exists in RTA, in other words, whether a non-equilibrium thermodynamic structure exists in quantum coherence.

There is one major problem in solving this puzzle. Since entanglement entropy and quantum thermodynamics are based on entropy, the methods in information theory were directly applicable to them. The methods in the non-i.i.d. regime, including information-spectrum theory [34] and its extension to quantum setups [35–39] such as quantum data compression and quantum cryptography, are well developed for entropy and were powerful tools to extend entanglement theory and quantum thermodynamics to the non-i.i.d. regime [29–31, 40, 41]. However, QFI is entirely different from entropy. Therefore, information-spectrum theory is not directly applicable to energetic coherence.

In this Letter, we solve this problem by constructing an information spectral method valid for QFI. As a consequence, we establish the theory of convertibility between pure states in RTA in the non-i.i.d. regime. Our concrete contributions are the following three. First, we introduce new quantities, termed the spectral sup- and inf-QFI rates, as counterparts in RTA to the spectral sup- and inf-entropy rates. The spectral QFI rates play fundamental roles in the non-i.i.d. regime. More precisely, we show that the optimal conversion rates of a sequence of arbitrary pure states from and to a reference state in RTA, i.e., the coherence cost and the distillable coherence, are given by the spectral sup- and inf-QFI rates, respectively.

Second, to construct the spectral sup- and inf-QFI rates through the smoothing method, we define the max- and min-QFI. These are the counterparts in RTA to the max- and min-entropies. They quantify the amounts of coherence in a state that can be transformed from and to a pure state whose energy distribution is given by a Poisson distribution.

Third, to show the properties of the max- and min-QFI, we introduce the notion of asymmetric majorization for probability distributions. Similar to ordinary majorization, asymmetric majorization is a preorder. We show that the exact convertibility between pure states in RTA is expressed by an asymmetric majorization relation between energy distributions. This theorem is the counterpart in RTA to Nielsen’s theorem [42], which states that the convertibility between bipartite pure states in entanglement theory is characterized by the majorization relation of the Schmidt coefficients.

Our findings indicate that the Fisher information content and its variations in RTA play precisely the same role as the entanglement entropy and its relatives in entanglement theory. It clarifies that the theory of energetic coherence in the non-i.i.d. regime has a structure similar to Lieb-Yngvason’s non-equilibrium thermodynamics, based on QFI rather than entropy.

**Resource theory of asymmetry (RTA).—** As stated in Introduction, this Letter aims to construct a general theory of distillation and dilution of energetic coherence. To this end, we begin by identifying states with and without energetic coherence. Consider a quantum system $S$ and its Hamiltonian $H$. Then the energy eigenstates are determined by this Hamiltonian. Energetic coherence means superposition of different energy eigenstates. Thus, a state $\rho$ has energetic coherence if and only if it is changed by the time evolution $e^{-iHt}$. Conversely, a state without energetic coherence is symmetric with respect to this time evolution $e^{-iHt}$: $e^{-iHt}\rho e^{iHt} = \rho$ for any $t \in \mathbb{R}$. From these facts, we call a state without energetic coherence a symmetric state and a state with energetic coherence an asymmetric state. By definition, a state $\rho$ is symmetric if and only if $[\rho, H] = 0$.

We next consider transformations of states with energetic coherence. A basic element is an operation which does not create energetic coherence in the sense that it transforms a symmetric state to a symmetric state. This condition is satisfied if the operation is described by a CPTP map $\mathcal{E}$ satisfying [43]

$$\mathcal{E}(e^{-iHt}\rho e^{iHt}) = e^{-iHt}\mathcal{E}(\rho)e^{iHt}, \ \forall \rho, \forall t \in \mathbb{R}. \quad (1)$$

A channel $\mathcal{E}$ satisfying Eq. (1) is called covariant (under time evolution $e^{-iHt}$).

Based on the above ideas, a resource theory of energetic coherence can be constructed, i.e., the resource theory of asymmetry (RTA). The framework of a resource theory is determined by defining “free states” that can be freely prepared and “free operations” that can be freely performed. In RTA, symmetric states are free states, and covariant operations are free operations. With these definitions, energetic coherence in asymmetric states becomes a resource. This structure in RTA is the same as in the entanglement theory, where entanglement becomes a resource by defining separable states and local operations and classical communication (LOCC) as free states and free operations.

The resource theoretic viewpoint suggests that the amount of coherence is quantified by resource measures, which monotonically decrease under a covariant operation. A well-known and important one is the symmetric logarithm derivative Fisher information [44, 45] with respect to $\{e^{-iHt}\rho e^{iHt}\}$, given by

$$\mathcal{F}(\rho, H) := 2 \sum_{i,j} \left(\frac{\lambda_i - \lambda_j}{\lambda_i + \lambda_j}\right)^2 |\langle i |H|j \rangle|^2, \quad (2)$$

where $\rho = \sum_i \lambda_i |i\rangle \langle i|$ is the eigenvalue decomposition. See, e.g., [46, 47] for details and its generalization. In the following, we call this quantity quantum Fisher information (QFI), which is simply written as $\mathcal{F}(\rho)$. It is known that QFI is given by the convex roof of variance: $\mathcal{F}(\rho) = 4 \min(q_i, \phi_i) q_i V_{\phi_i}(H)$, where $\{q_i, \phi_i\}$ runs over the set of all probability distributions $\{q_i\}$ and pure states $\{\phi_i\}$ such that $\rho = \sum_i q_i \phi_i$ [48, 49]. Here, $V_{\phi_i}(H)$...
denotes the variance of $H$ in $\phi_i$. This property shows that QFI quantifies the minimum average quantum fluctuation over the ensemble. For a pure state, QFI equals four times the variance of $H$.

Following the standard argument [26], in the rest of this Letter, we will analyze a system with a Hamiltonian

$$H = \sum_{n=0}^{\infty} n \ket{n} \bra{n},$$

where $\{|n\rangle\}$ denotes an orthogonal basis. We remark that using the method in Ref. [26], results given for the Hamiltonian (3) can be extended to a more general setup in RTA with arbitrary Hamiltonians [50].

An essential characteristic of a pure state $\psi = |\psi\rangle \langle \psi|$ in the manipulation of energetic coherence is its energy distribution $p_\psi = \{p_\psi(n)\}_{n=0}^{\infty}$, where $p_\psi(n) := |\langle n | \psi \rangle|^2$. This is because any pure state $|\psi\rangle$ can be mapped to $\sum_{n=0}^{\infty} \sqrt{p_\psi(n)} |n\rangle$ by an energy-conserving unitary operation, which is covariant and invertible. In fact, necessary and sufficient conditions for the exact convertibility between pure states have been obtained in terms of the energy distributions [23, 25, 51].

From a practical viewpoint, the exact conversion is typically impossible and too restrictive. Therefore, it is common to explore the convertibility with vanishing error in the asymptotic regime. We adopt the trace distance $D(\rho, \sigma) := \frac{1}{2} \|\rho - \sigma\|_1$ as a quantifier of error, where $\|A\|_1 := \text{Tr}(\sqrt{A^*A})$.

We say that a sequence of states $\rho = \{\rho_m\}_{m=0}^{\infty}$ can be asymptotically converted to another sequence of states $\sigma = \{\sigma_m\}_{m=0}^{\infty}$ by covariant operations if and only if there exists a sequence of covariant operations $E = \{E_m\}_{m=0}^{\infty}$ such that $\lim_{m \to \infty} D(E_m(\rho_m), \sigma_m) = 0$. In this case, we denote $\rho \succeq \sigma$. Here, we also assume that the Hamiltonians for the input and the output systems are given by Eq. (3). For the same reason as in the one-shot case, the results on convertibility in this setup can be extended to a more general setup with arbitrary Hamiltonians [50]. Of course, this includes the i.i.d. case, where a Hamiltonian is given by a sum of copies of a free Hamiltonian of a subsystem.

In the analysis of asymptotic convertibility, we adopt a coherence bit $|\phi_{coh}\rangle := (|0\rangle + |1\rangle)/\sqrt{2}$ as a reference. There are two fundamental resource measures: the coherence cost and the distillable coherence. They are defined as optimal rates for converting a sequence of states from and to coherence bits, respectively. Precisely, we define

$$C_{\text{cost}}(\rho) := \inf \left\{ R \mid \rho_{\text{coh}}(R) \succeq \tilde{\rho} \right\}, \quad C_{\text{dist}}(\rho) := \sup \left\{ R \mid \tilde{\rho} \succeq \rho_{\text{coh}}(R) \right\},$$

where $\rho_{\text{coh}}(R) := \{\rho_{\text{coh}}[Rm]\}_m$ for $R > 0$. Note that the infimum of the empty set is formally defined as $+\infty$.

Finally, for later convenience, we introduce several notations for sequences of numbers. For sequences $a = \{a(n)\}_{n \in \mathbb{Z}}$ and $b = \{b(n)\}_{n \in \mathbb{Z}}$, if and only if two sequences are the same, i.e., $a(n) = b(n)$ for all $n \in \mathbb{Z}$, we denote $a = b$. We denote $a \geq 0$ if and only if $a(n) \geq 0$ for all $n \in \mathbb{Z}$. We also define a product sequence $a \ast b$ by $a \ast b(n) := \sum_{k \in \mathbb{Z}} a(k)b(n - k)$. Similarly, we define $[a \ast b]_n(n) := \sum_{k=m}^{n} a(k)b(n - k)$.

For a given sequence $q = \{q(n)\}_{n \in \mathbb{Z}}$, another sequence $\tilde{q} = \{\tilde{q}(n)\}_{n \in \mathbb{Z}}$ satisfying

$$\delta_{0,n} = \tilde{q} \ast q(n)$$

plays a central role in our analysis. Here, $\delta_{m,n}$ is the Kronecker delta. If there exists a finite $n_* := \min\{n \mid q(n) > 0\}$, such a sequence is constructed as

$$\tilde{q}(n) := \begin{cases} 0 & (n < -n_*) \\ \frac{1}{q(n_*)} & (n = -n_*) \\ -\frac{1}{q(n_*)} \tilde{q} \ast q|_{n_*-1}^n(n_* + n) & (n > -n_*) \end{cases}$$

In particular, if $q$ is an energy distribution, $n_* \geq 0$ exists. Note that $\tilde{q}(n)$ is defined recursively for $n > -n_*$. We also introduce a generalized Poisson distribution

$$P_\lambda = \{P_\lambda(n)\}_{n \in \mathbb{Z}}$$

as a sequence parameterized by $\lambda \in \mathbb{R}$, where $P_\lambda(n) := e^{-\lambda} \lambda^n / n!$ for $n \geq 0$ and $P_\lambda(n) := 0$ for $n < 0$. For $\lambda \geq 0$, $P_\lambda$ is a Poisson distribution, while for $\lambda < 0$, it is not a probability distribution since $P_\lambda(n) < 0$ if $n$ is a positive odd number. Nevertheless, $P_\lambda$ with negative $\lambda$ is useful since $P_\lambda = P_{-\lambda}$ [50].

**Main results.**— Now, let us construct an information-spectrum theory for QFI and show our main results. We first introduce key quantities to analyze the convertibility. For a pure state $\psi$, we define the max- and min-QFI, denoted by $F_{\text{max}}(\psi)$ and $F_{\text{min}}(\psi)$, as

$$F_{\text{max}}(\psi) := \inf \left\{ 4\lambda \mid P_\lambda \ast \rho_{\text{co}} \geq 0 \right\}, \quad F_{\text{min}}(\psi) := \sup \left\{ 4\lambda \mid \psi \ast P_{-\lambda} \geq 0 \right\}.$$
For a general sequence of pure states \( \hat{\psi} = \{ \psi_m \} \), the spectral sup- and inf-QFI rates are defined as
\[
\mathcal{F}(\psi) := \lim_{\epsilon \to 0^+} \lim_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{max}}(\psi_m),
\]
\[
\mathcal{F}(\hat{\psi}) := \lim_{\epsilon \to 0^+} \liminf_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{min}}(\psi_m),
\]
where \( \mathcal{F}_{\text{max}}(\psi) := \inf_{\rho \in B(\psi)} \mathcal{F}_{\text{max}}(\rho) \) and \( \mathcal{F}_{\text{min}}(\psi) := \sup_{\rho \in B(\psi)} \mathcal{F}_{\text{min}}(\rho) \) are smooth max- and min-QIF.

Here, we defined \( B'(\psi) := \{ \rho : \text{states} | D(\rho, \psi) \leq \epsilon \} \) and \( B'_\text{pure}(\psi) := \{ \phi : \text{pure states} | D(\phi, \psi) \leq \epsilon \} \).

It should be noted that \( \lim_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{max}}(\psi_m) \) and \( \liminf_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{min}}(\psi_m) \) monotonically increase and decreases as \( \epsilon \) becomes smaller, and hence limit values \( \mathcal{F}(\psi) \) and \( \hat{\mathcal{F}}(\hat{\psi}) \) exist.

The main theorem of this Letter is the following:

**Theorem 1.** For a general sequence of pure states \( \hat{\psi} = \{ \psi_m \} \), the coherence cost and the distillable coherence are equal to the spectral sup- and inf-QFI rates, respectively. That is,
\[
C_{\text{cost}}(\hat{\psi}) = \mathcal{F}(\hat{\psi}), \quad C_{\text{dist}}(\hat{\psi}) = \hat{\mathcal{F}}(\hat{\psi}).
\]

As a corollary of Theorem 1, we immediately get [50]
\[
\hat{\psi} \succ \phi \implies \mathcal{F}(\hat{\psi}) \geq \mathcal{F}(\phi), \quad \hat{\mathcal{F}}(\hat{\psi}) \geq \mathcal{F}(\hat{\phi}).
\]
\[
\mathcal{F}(\hat{\psi}) > \mathcal{F}(\phi) \implies \hat{\psi} \succ \phi.
\]

Replacing \( \hat{\mathcal{F}}, \hat{\mathcal{F}} \) and \( \succ \) by \( \mathcal{S}, \mathcal{S} \) and \( \succ \), the same relations as Eqs. (14) and (15) hold in entanglement theory. Here, \( \mathcal{S} \) and \( \mathcal{S} \) denote the spectral sup- and inf-entropy rates, while \( \psi \succ \phi \) means that \( \psi \) is asymptotically converted to \( \phi \) by LOCC [50].

If \( \hat{\psi} = \{ \psi_m^{\otimes m} \} \) for a pure state \( \psi \), it is known [26] that \( C_{\text{cost}}(\hat{\psi}) = C_{\text{dist}}(\hat{\psi}) = \mathcal{F}(\psi) \). From Theorem 1, we get \( \mathcal{F}(\hat{\psi}) = \mathcal{F}(\psi) = \hat{\mathcal{F}}(\hat{\psi}) \) in the i.i.d. regime. We remark that \( \mathcal{S} \) and \( \mathcal{S} \) are equal to entanglement entropy in the i.i.d. regime in entanglement theory [50].

These results show that the spectral sup- and inf-Fisher information rates, \( \mathcal{F} \) and \( \mathcal{F} \), in RTA play the same roles as the spectral sup- and inf-entropy rates, \( \mathcal{S} \) and \( \mathcal{S} \), in entanglement theory [50]. See Fig. 1. In other words, RTA in the non-i.i.d. regime has the same structure as Lieb-Yngvason’s non-equilibrium theory [32], based on QFI-related quantities rather than entropies.

Theorem 1 for the coherence cost is directly extended to general states, including mixed states. That is, defining \( \hat{\mathcal{F}}(\hat{\rho}) := \lim_{\epsilon \to 0^+} \limsup_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{max}}(\rho_m) \), where \( \mathcal{F}_{\text{max}}(\rho) := \inf_{\sigma \in B(\rho)} \mathcal{F}_{\text{max}}(\sigma) \), the following holds [50]:

**Theorem 2.** For a general sequence of states \( \hat{\rho} = \{ \rho_m \} \), it holds \( C_{\text{cost}}(\hat{\rho}) = \mathcal{F}(\hat{\rho}) \).

---

**FIG. 1.** Comparison of entanglement theory and RTA on the asymptotic convertibility. In entanglement theory, a sequence of i.i.d. pure states is given by \( \psi = \{ \psi^{\otimes m} \} \) and \( \rho(\psi) \) denotes the von Neumann entropy of the reduced state \( \rho := \text{Tr}_B(\psi_{AB}) \). In the non-i.i.d. regime, sequences of general pure states and reduced states are denoted by \( \hat{\psi} = \{ \psi_{AB,m} \} \) and \( \hat{\rho} = \{ \rho_m \} \), where \( \rho_m := \text{Tr}_B(\psi_{AB,m}) \). The smooth max- and min-entropies are denoted by \( S_{\text{max}}(\rho) \) and \( S_{\text{min}}(\rho) \). The quantities \( E_{\text{cost}} \) and \( E_{\text{dist}} \) denote the entanglement cost and the distillable entanglement. See [50] for a short summary on entanglement theory.

---

**One-shot convertibility between pure states.**—We here define a notion of asymmetric majorization, which we will abbreviate a-majorization, as follows:

**Definition 3.** For probability distributions \( p = \{ p(n) \}_{n \in \mathbb{Z}} \) and \( q = \{ q(n) \}_{n \in \mathbb{Z}} \), we say that \( p \) a-majorizes \( q \) if and only if \( p \ast q \geq 0 \) hold. In this case, we denote \( p \succ_a q \).

For comparison, we review the definition of majorization. A probability distribution \( p = \{ p(i) \}_{i=1}^d \) majorizes another probability distribution \( q = \{ q(i) \}_{i=1}^d \) if and only if \( \sum_{l=1}^k \begin{pmatrix} d \end{pmatrix}_l \geq \sum_{l=1}^k \begin{pmatrix} 0 \end{pmatrix}_l \) for all \( k = 1, \ldots, d \), where \( \begin{pmatrix} t \end{pmatrix}_l \) indicates that the distributions are rearranged in decreasing order so that \( p^i(i) \geq p^j(j) \) and \( q^i(i) \geq q^j(j) \) for \( i > j \).

The a-majorization has properties similar to the ordinary majorization [50]. Among them, a significant one is the following:

**Theorem 4.** A pure state \( \psi \) is converted to a pure state \( \phi \) by a covariant operation if and only if \( p_\phi \succ_a p_\psi \).

This is the counterpart in the RTA to Nielsen’s theorem in entanglement theory [42]: A bipartite pure state \( \psi \) is converted to a bipartite pure state \( \phi \) by LOCC if and only if \( \lambda_\psi < \lambda_\phi \), where \( \lambda_\psi \) and \( \lambda_\phi \) are the probability distributions whose elements are given by the Schmidt coefficients of \( \psi \) and \( \phi \), respectively. See Fig. 2.

We remark that other necessary and sufficient conditions on one-shot convertibility in RTA were proven in earlier studies [23, 25, 51]. Our contribution here is to provide the one-shot convertibility condition in terms of a-majorization to make it useful for our purpose to analyze the asymptotic convertibility in the non-i.i.d. regime. In particular, this reformulation makes the
correspondence between RTA and entanglement theory clearer.

**Proof of Theorem 1.**— In the following, we denote \( \rho \approx \sigma \) if two states \( \rho \) and \( \sigma \) satisfy \( D(\rho, \sigma) \leq \epsilon \). For two sequences of states \( \rho = \{ \rho_m \}_m \) and \( \sigma = \{ \sigma_m \}_m \), we denote \( \rho \approx \sigma \) if there exists a sequence of covariant channels \( \{ \mathcal{E}_m \}_m \) such that \( \mathcal{E}_m(\rho_m) \approx \sigma_m \) for all sufficiently large \( m \). For a Poisson distribution \( P_\lambda \), we define \( \lambda_n := \sum_{n=0}^{\infty} P_\lambda(n)/n! \) and \( \lambda_m := \{ \lambda_m \}_m \). This state can be converted to and from \( \phi_{\text{coh}}(R) \) by covariant operations. That is, \( \phi_{\text{coh}}(R) \approx \epsilon \hat{\lambda}_{R/4} \) and \( \hat{\lambda}_{R/4} \approx \epsilon \phi_{\text{coh}}(R) \) for an arbitrary \( \epsilon > 0 \) [50].

The followings are key lemmas [50]:

**Lemma 5.** Let \( \mathcal{E} \) be a covariant channel. A state \( \mathcal{E}(\chi) \) has a purification \( \Psi \) such that \( \rho_{\Psi} = \rho_{\lambda} \), where the Hamiltonian of the auxiliary system that is added to purify \( \mathcal{E}(\chi) \) has integer eigenvalues.

**Lemma 6.** Let \( \psi \) and \( \phi \) be pure states. Assume that a covariant channel satisfies \( \mathcal{E}(\psi) \approx \phi \). Then there exists a pure state \( \psi' \) such that \( \psi' \in B_{\text{pure}}(\chi) \) and \( \psi' \approx \phi \).

To show \( C_{\text{cost}}(\hat{\psi}) = \mathcal{F}(\hat{\psi}) \), let us define \( C_{\text{cost}}(\rho) := \inf \{ R \mid \phi_{\text{coh}}(R) \approx \epsilon \hat{\psi} \} \). Defining \( 4\lambda/2 \approx C_{\text{cost}}(\hat{\psi}) \), for any parameter \( \delta > 0 \), there exists a real number \( \delta' > 0 \) such that \( \delta > \delta' > 0 \) and \( \phi_{\text{coh}}(4\lambda/2 + \delta') \approx \epsilon \hat{\psi} \). Since \( \hat{\lambda}_{(\lambda/2 + \delta')} \approx \epsilon \phi_{\text{coh}}(4\lambda/2 + \delta') \), we have \( \hat{\lambda}_{(\lambda/2 + \delta')} \approx \epsilon \hat{\psi} \), where we have used the fact that \( P_{\lambda} \approx \hat{\lambda}_{\lambda} \) holds for any \( \lambda \geq \lambda' \) [50]. From Lemma 5, for all sufficiently large \( m \), there exists a state \( \rho_m \in B(\psi_m) \) whose purification \( \Phi_m \) satisfies \( P_{\lambda/2 + \delta_m} \approx \phi_{\text{coh}}(\lambda/2 - \delta) \). Therefore, \( 4\lambda/2 + \delta_m \geq \mathcal{F}_{\text{max}}(\hat{\psi}) \) for sufficiently large \( m \), which implies

\[
C_{\text{cost}}(\hat{\psi}) + 4\delta \geq \lim_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{max}}(\psi_m). \tag{16}
\]

Since \( \delta = \delta_m \geq 0 \), such that there exists a state \( \rho_m \in B^{\lambda/2}(\psi_m) \) and its purification \( \Phi_m \approx \phi_{\text{coh}}(\lambda/2 + \delta_m) \). Note that for all sufficiently large \( m \), \( m(\lambda/2 + \delta) \geq \lambda/2 \) holds for \( \lambda/2 := \lim_{m \to \infty} \frac{1}{m} \lambda_m/2 \). Therefore, we get \( P_{\lambda/2 + \delta_m} \approx \phi_{\text{coh}}(4\lambda/2 + 2\delta) \) for sufficiently large \( m \). Since the partial trace is a covariant operation, we have \( \phi_{\text{coh}}(4\lambda/2 + 2\delta) \approx \phi_{\text{coh}}(4\lambda/2 + 2\delta) \). Therefore,

\[
C_{\text{cost}}(\hat{\psi}) \leq \lim_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{max}}(\psi_m) + 8\delta. \tag{17}
\]

Since \( \delta > 0 \) is arbitrary, we get \( C_{\text{cost}}(\hat{\psi}) \leq \mathcal{F}(\hat{\psi}) \).

To show \( C_{\text{dist}}(\hat{\psi}) = \frac{1}{m} \mathcal{F}_{\text{min}}(\psi_m) \), let us define \( C_{\text{dist}}(\hat{\psi}) := \frac{1}{m} \mathcal{F}_{\text{min}}(\psi_m) \). Defining \( 4\lambda/2 := C_{\text{dist}}(\hat{\psi}) \), for an arbitrary parameter \( \delta > 0 \), there exists a nonnegative number \( \delta' \) such that \( \delta > \delta' > 0 \) and \( \phi_{\text{coh}}(4\lambda/2 + \delta') \). Since \( \phi_{\text{coh}}(4\lambda/2 + \delta') \approx \epsilon \hat{\lambda}_{\lambda/2 + \delta'} \), we get \( \psi_m \approx \phi_{\text{coh}}(4\lambda/2 + 2\delta) \). For all sufficiently large \( m \), there exist pure states \( \psi'_m \in B_{\text{pure}}(\psi_m) \) such that \( \psi'_m \approx \phi_{\text{coh}}(4\lambda/2 + 2\delta) \), where we used \( \delta > \delta' \). Therefore,

\[
C_{\text{cost}}(\hat{\psi}) - 4\delta \leq \lim_{m \to \infty} \frac{1}{m} \mathcal{F}_{\text{min}}(\psi_m). \tag{18}
\]

Since \( \delta > 0 \) is arbitrary, we get \( C_{\text{dist}}(\hat{\psi}) \leq \mathcal{F}(\hat{\psi}) \).

**Conclusion and Discussions.**— In this Letter, we established the asymptotic convertibility theory in RTA in the non-i.i.d. regime. To obtain this result, we extended the information spectral method to a form applicable to quantum Fisher information. We first define the max- and min-QFI, which are the counterparts in RTA to the max- and min-entropies. They quantify the amounts of coherence in a state that can be transformed from and to a state whose energy distribution is given by a Poisson distribution. By smoothing the max- and min-QFI,
we obtain the spectral sup- and inf-QFI rates as counterparts in RTA to the spectral sup- and inf-entropy rates. The spectral QFI rates are precisely equal to the optimal conversion rates of a sequence of pure states from and to a reference state by covariant operations, i.e., the coherence cost and the distillable coherence.

Our result shows that the correspondence between QFI in RTA and entanglement entropy in entanglement theory is valid even in the non-i.i.d. regime. It indicates that the theory of energetic coherence has a structure similar to Lieb-Yngvason’s nonequilibrium thermodynamics, which is based on QFI instead of entropy.

[43] In fact, any completely incoherence-preserving operation satisfies Eq. (1) [5]. Here, a channel $\mathcal{E}$ is called completely incoherence-preserving if and only if for any ancillary system $A$ with an arbitrary Hamiltonian $H_A$, the map $\mathcal{E} \otimes I_A$ transforms any symmetric state to a symmetric state, where $I_A$ denotes the identity map on $A$.

Convertibility between pure states with finite periods

Here, based on the arguments in [23, 26], we show that the convertibility between pure states with finite periods can be analyzed with a system with the Hamiltonian in Eq. (3).

Let $S$ and $S'$ be quantum systems with Hamiltonians $H_S$ and $H_{S'}$. A quantum channel $\Lambda$ is called covariant if and only if

$$e^{-iH_{S'} t} (\Lambda(\rho_S)) e^{iH_{S'} t} = \Lambda(e^{-iH_S t} \rho_S e^{iH_S t})$$

(S.1)

holds for all states $\rho_S$ of the system $S$ and for all $t \in \mathbb{R}$.

Let us analyze the convertibility from a pure states $\psi_S$ of $S$ to a pure state $\phi_{S'}$ of $S'$. Define the period of $\psi_S$ as

$$\tau := \inf_{t \geq 0} \{ t | \langle \psi | e^{-iH_{S'} t} \psi \rangle = 1 \}.$$  (S.2)

Assuming that $\tau$ is finite and positive, a state $\psi_S$ is mapped by a covariant operation to a state with a finite period $\tau / k$ for some positive integer $k$. Therefore, we assume that $\phi_{S'}$ has a finite period $\tau' = \tau / k$ with some positive integer $k$. 
Let $H_S = \sum_{E \in \text{Spec}(H_S)} E \Pi^{(S)}_E$ be the spectrum decomposition of the Hamiltonian. When a pure state $\psi_S$ has a finite period $\tau$, the Hamiltonian is decomposed into two parts:

$$H_S = \sum_{n=0}^{\infty} \left( \frac{2\pi}{\tau} n + E_0 \right) \Pi^{(S)}_{\frac{2\pi}{\tau} n + E_0} + \sum_{x \in \mathcal{X}} x \Pi^{(S)}_x,$$

where $\Pi^{(S)}_x |\psi\rangle = 0$ for all $x \in \mathcal{X}$. By shifting the Hamiltonian, we can always set $E_0 = 0$. Here, for a general setup, the set $\text{Spec}(H_S)$ may not contain $\frac{2\pi}{\tau} n + E_0$ for all nonnegative integers $n$. In this case, defining $\Pi^{(S)}_{\frac{2\pi}{\tau} n + E_0} = 0$ for $n$ such that $\frac{2\pi}{\tau} n + E_0 \notin \text{Spec}(H_S)$, the expansion in Eq. (S.3) is valid. Shifting the Hamiltonian by a constant, without loss of generality, we can set $E_0 = 0$.

In the same way, when a pure state $\phi_{S'}$ has a finite period $\tau' = \tau/k$, the Hamiltonian is expanded as

$$H_{S'} = \sum_{n=0}^{\infty} \left( \frac{2\pi}{\tau'} n + E_0^{(S')} \right) \Pi^{(S')}_{\frac{2\pi}{\tau'} n + E_0^{(S')}} + \sum_{x' \in \mathcal{X}'} x' \Pi^{(S')}_{x'} = k \sum_{n=0}^{\infty} \left( \frac{2\pi}{\tau} n + E_0^{(S')} \right) \Pi^{(S')}_{\frac{2\pi}{\tau} n + E_0^{(S')}} + \sum_{x' \in \mathcal{X}'} x' \Pi^{(S')}_{x'},$$

where $\Pi^{(S')}_{x'} |\phi\rangle = 0$ for all $x' \in \mathcal{X}'$. Again, without loss of generality, we can set $E_0^{(S')} = 0$ by shifting the Hamiltonian by a constant.

By multiplying the Hamiltonians by $\tau/(2\pi)$, we get

$$H_S = \sum_{n=0}^{\infty} n \Pi^{(S)}_n + \sum_{x \in \mathcal{X}} x \Pi^{(S)}_x, \quad H_{S'} = \sum_{n=0}^{\infty} n \Pi^{(S')}_n + \sum_{x' \in \mathcal{X}'} x' \Pi^{(S')}_{x'},$$

Here, to simplify the notation in the first term in $H_{S'}$, we have defined $\Pi^{(S')}_n = 0$ for $n$ that is not an integer multiple of $k$.

For given pure states $|\psi\rangle_S$ and $|\phi\rangle_{S'}$, there always exist covariant unitary operations, i.e., energy-conserving unitary operations $U_S$ and $U_{S'}$ such that

$$U_S |\psi\rangle_S = \sum_{n=0}^{\infty} \sqrt{p_\psi(n)} |n\rangle_S := |\tilde{\psi}\rangle_S, \quad U_{S'} |\phi\rangle_{S'} = \sum_{n=0}^{\infty} \sqrt{p_\phi(n)} |n\rangle_{S'} := |\tilde{\phi}\rangle_{S'},$$

where

$$p_\psi(n) := \langle \psi | \Pi^{(S)}_n |\psi\rangle, \quad p_\phi(n) := \langle \phi | \Pi^{(S')}_n |\phi\rangle$$

are the energy distributions and $|n\rangle_S$ and $|n\rangle_{S'}$ are some eigenvectors with an eigenvalue $n$ [23]. Therefore, we will analyze the convertibility between $|\tilde{\psi}\rangle_S$ and $|\tilde{\phi}\rangle_{S'}$ instead of that between $|\psi\rangle_S$ and $|\phi\rangle_{S'}$.

Defining $\mathcal{H}^{(\psi)}_S := \text{Span}\{|n\rangle_S\}_{n=0}^{\infty}$ and $\mathcal{H}^{(\phi)}_{S'} := \text{Span}\{|n\rangle_{S'}\}_{n=0}^{\infty}$, the Hilbert spaces $\mathcal{H}_S$ and $\mathcal{H}_{S'}$ are decomposed into direct sums:

$$\mathcal{H}_S = \mathcal{H}^{(\psi)}_S \oplus \mathcal{H}^{(\psi)^\perp}_S, \quad \mathcal{H}_{S'} = \mathcal{H}^{(\phi)}_{S'} \oplus \mathcal{H}^{(\phi)^\perp}_{S'},$$

where the subspaces $\mathcal{H}^{(\psi)^\perp}_S$ and $\mathcal{H}^{(\phi)^\perp}_{S'}$ are spanned by vectors orthogonal to $\{ |n\rangle_S\}_{n=0}^{\infty}$ and $\{ |n\rangle_{S'}\}_{n=0}^{\infty}$, respectively. Similarly, the Hamiltonians are decomposed as

$$H_S = \sum_{n \in \mathbb{Z}} n |n\rangle \langle n|_S + Y_S, \quad H_{S'} = \sum_{n \in \mathbb{Z}} n |n\rangle \langle n|_{S'} + Y_{S'},$$

where $Y_S$ and $Y_{S'}$ are Hermitian operators on the subspaces $\mathcal{H}^{(\psi)^\perp}_S$ and $\mathcal{H}^{(\phi)^\perp}_{S'}$, respectively.

For a Hilbert space $\mathcal{H}$, let $\mathcal{L}(\mathcal{H})$ be the set of all linear operators on $\mathcal{H}$. To analyze the convertibility, let $\Lambda : \mathcal{L}(\mathcal{H}_S) \rightarrow \mathcal{L}(\mathcal{H}_{S'})$ be a covariant channel. Defining a map

$$\mathcal{E}(\cdots) := \Pi^{(\phi)} \left( \Lambda \left( \Pi^{(\psi)} (\cdots) \Pi^{(\psi)} \right) \Pi^{(\phi)} \right) \mathcal{L} \left( \mathcal{H}^{(\phi)}_S \right) \rightarrow \mathcal{L} \left( \mathcal{H}^{(\phi)}_{S'} \right),$$

where

$$\Pi^{(\psi)} := \sum_{n=0}^{\infty} |n\rangle \langle n|_S, \quad \Pi^{(\phi)} := \sum_{n=0}^{\infty} |n\rangle \langle n|_{S'},$$

(10.11)
it is clear that $\mathcal{E}$ is a covariant channel with respect to Hamiltonians $\sum_{n=0}^{\infty} n \left| n \right\rangle_{S}$ and $\sum_{n=0}^{\infty} n \left| n \right\rangle_{S'}$. Furthermore, it satisfies

$$D \left( \Lambda \left( \psi, \phi \right), \phi \right) = D \left( \mathcal{E} \left( \psi \right), \phi \right). \quad (S.12)$$

Conversely, for a given covariant channel $\mathcal{E}' : \mathcal{L} \left( \mathcal{H}_{S}^{(\psi)} \right) \to \mathcal{L} \left( \mathcal{H}_{S'}^{(\psi)} \right)$, define a map

$$\Lambda' \left( \ldots \right) := \mathcal{E}' \left( \Pi (\psi) \left( \ldots \right) \Pi (\psi) \right) + \text{Tr} \left( \left( \ldots \right) \left( \mathbb{I}_{S} - \Pi (\psi) \right) \right) \chi : \mathcal{L} \left( \mathcal{H}_{S} \right) \to \mathcal{L} \left( \mathcal{H}_{S'} \right), \quad (S.13)$$

where $\chi$ is an eigenvector of $Y_{S'}$. This map $\Lambda'$ is a covariant channel with respect to the Hamiltonians $H_{S}$ and $H_{S'}$. In addition, it satisfies

$$D \left( \Lambda' \left( \psi, \phi \right), \phi \right) = D \left( \mathcal{E}' \left( \psi \right), \phi \right). \quad (S.14)$$

Therefore, instead of the convertibility from $\psi$ to $\phi$ with an error, we can analyze the convertibility from $\tilde{\psi}$ to $\tilde{\phi}$ with the Hamiltonian in the form of $\sum_{n=0}^{\infty} n \left| n \right\rangle \left\langle n \right|$.

In analyses of asymptotic convertibility, the same argument is valid. Suppose that we want to investigate the convertibility from a sequence of pure states $\tilde{\psi} = \{ \psi_{m} \}_{m}$ to another sequence of pure states $\tilde{\phi} = \{ \phi_{m} \}_{m}$. We assume that the periods

$$\tau_{m} := \inf_{t>0} \left\{ t \left| \left\langle \psi_{m} \left| e^{-iH_{m}(S)}t \right| \psi_{m} \right\rangle = 1 \right\}, \quad \tau'_{m} := \inf_{t>0} \left\{ t \left| \left\langle \phi_{m} \left| e^{-iH_{m}'(S')t} \right| \phi_{m} \right\rangle = 1 \right\} \quad (S.15)$$

are finite and satisfy $\tau'_{m} = \tau_{m}/k_{m}$ for some positive integer $k_{m}$. Applying the above argument for each $m$, without loss of generality, we can analyze the convertibility under the assumption that all the Hamiltonians are given by $\sum_{n=0}^{\infty} n \left| n \right\rangle \left\langle n \right|$.

The generating function of the Poisson distribution and its reciprocal

For a sequence $q = \{ q(n) \}_{n \in \mathbb{Z}}$, we have defined $\tilde{q}$ as a sequence that satisfies Eq. (6). Although it can be constructed recursively by Eq. (7), the method of the generating function [52] is sometimes useful. For simplicity, we assume that $n_{*} = 0$. That is, $q(n) = 0$ for $n < 0$ and $q(0) \neq 0$. A generating function of $q = \{ q(n) \}_{n=0}^{\infty}$ is defined as a formal series given by

$$f(z) := \sum_{n=0}^{\infty} q(n) z^{n}. \quad (S.16)$$

Its reciprocal $1/f(z)$ that satisfies

$$1 = f(z) \times 1/f(z) \quad (S.17)$$

for all $z$ exists if and only if $q(0) \neq 0$ [52]. Let $a = \{ a(n) \}_{n=0}^{\infty}$ be a sequence generated by $1/f(z)$. From Eq. (S.17), it satisfies

$$\delta_{0} = a \ast q, \quad (S.18)$$

where we have defined $a(n) = 0$ for $n < 0$ and $\delta_{0}$ as a sequence defined by $\delta_{0} = \{ \delta_{n,0} \}_{n \in \mathbb{Z}}$. In other words, $a$ is the same as the sequence $\tilde{q}$ defined in Eq. (7). We remark that a similar technique, based on characteristic functions instead of generating functions, has been used in [25, 51] to derive a necessary and sufficient condition on the one-shot convertibility in RTA.

Let us apply this method to the Poisson distribution. For a sequence $\{ P_{\lambda}(n) \}_{n=0}^{\infty}$, its generating function is calculated as

$$f(z) = \sum_{n=0}^{\infty} P_{\lambda}(n) z^{n} = e^{-\lambda} e^{\lambda z}. \quad (S.19)$$
Therefore, its reciprocal is given by

$$1/f(z) = e^{-(\lambda)}e^{(-\lambda)z}.$$  \hfill (S.20)

Since

$$\sum_{n=0}^{\infty} e^{-(\lambda)} \frac{(-\lambda)^n}{n!} z^n = e^{-(\lambda)}e^{(-\lambda)z} = 1/f(z),$$  \hfill (S.21)

the sequence generated by $1/f(z)$ is given by $\{P_{-\lambda}(n)\}_{n=0}^{\infty}$. That is, $\tilde{P}_{\lambda} = P_{-\lambda}$.

This result can also be checked directly: Let $\lambda$ and $\lambda'$ be real parameters. A straightforward calculation shows that

$$\sum_{k \in \mathbb{Z}} P_{\lambda}(k)P_{\lambda'}(n - k) = \left(\sum_{k \in \mathbb{Z}} \tilde{P}_{\lambda}(k)\right) \left(\sum_{n \in \mathbb{Z}} q(n)\right),$$  \hfill (S.22)

$$= P_{\lambda + \lambda'}(n).$$  \hfill (S.23)

Since $P_0 = \delta_0$, we get $\tilde{P}_{\lambda} = P_{-\lambda}$.

Another immediate consequence of Eq. (S.23) is the fact that

$$\lambda \geq \lambda' \geq 0 \iff P_{\lambda} \succ_a P_{\lambda'}.$$  \hfill (S.24)

This is because $P_{\sigma}(n)$ is non-negative for all $n$ if and only if $\sigma \geq 0$.

**Proof of Theorem 4**

To prove Theorem 4, a key theorem is the following:

**Theorem 7.** For two probability distributions $\{p(n)\}_{n=0}^{\infty}$ and $\{q(n)\}_{n=0}^{\infty}$, conditions (i) and (ii) are equivalent:

(i) There exists a probability distribution $\{w(k)\}_{k \in \mathbb{Z}}$ such that $p = \sum_{k \in \mathbb{Z}} w(k)\Upsilon_k q$, where $\Upsilon_k$ is a shift operator on probability distribution such that $(\Upsilon_k p)(n) = p(n - k)$.

(ii) $p \succ_a q$.

This theorem corresponds to the Hardy-Littlewood-Pólya theorem [53] in the theory of majorization, which states that the following conditions (a) and (b) are equivalent: (a) There exists a double stochastic matrix $D$ such that $p = D q$. (b) $p$ majorizes $q$, i.e., $p \succ q$. The correspondence becomes more clear by using Birkhoff’s theorem [54], which states that any double stochastic matrix $D$ can be written as $D = \sum_k r(k)P_k$, where $\{r(k)\}$ is a probability distribution, $P_k$ are the permutation matrices, and the sum is taken over the set of all permutation matrices. For details, see, e.g., [55].

**Proof of Theorem 7.** For a probability distribution $\{q(n)\}_{n \in \mathbb{Z}}$, the sequence $\tilde{q}$ defined in Eq.(7) satisfies Eq. (6). Therefore,

$$\sum_{n \in \mathbb{Z}} \delta_0(n) = \sum_{n \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} \tilde{q}(k)q(n - k) = \left(\sum_{k \in \mathbb{Z}} \tilde{q}(k)\right) \left(\sum_{n \in \mathbb{Z}} q(n)\right),$$  \hfill (S.25)

which implies

$$\sum_{k \in \mathbb{Z}} \tilde{q}(k) = \frac{1}{\sum_{n \in \mathbb{Z}} q(n)} = 1.$$  \hfill (S.26)
For a probability distribution $p = \{p(n)\}_{n \in \mathbb{Z}}$, from Eq. (6), we have
\[ p(n) = \sum_{l \in \mathbb{Z}} \delta_0(n - l)p(l) \]
\[ = \sum_{l \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} \tilde{q}(k)q(n - l - k)p(l) \quad (S.27) \]
\[ = \sum_{k \in \mathbb{Z}} \left( \sum_{l \in \mathbb{Z}} p(l)\tilde{q}(k - l) \right) q(n - k) \quad (S.28) \]
\[ = \sum_{k \in \mathbb{Z}} (p * \tilde{q})(k)q(n - k). \quad (S.29) \]

In addition,
\[ \sum_{k \in \mathbb{Z}} (p * \tilde{q})(k) = \sum_{l \in \mathbb{Z}} p(l) \sum_{k \in \mathbb{Z}} \tilde{q}(k - l) = 1 \quad (S.30) \]

holds since $\sum_{k \in \mathbb{Z}} p(k) = \sum_{k \in \mathbb{Z}} \tilde{q}(k) = 1$.

Suppose that
\[ p(n) = \sum_{k \in \mathbb{Z}} w(k)q(n - k) \quad (S.31) \]
holds for some $w = \{w(k)\}_{k \in \mathbb{Z}}$. Then we have
\[ \sum_{l \in \mathbb{Z}} p(l)\tilde{q}(k - l) = \sum_{l \in \mathbb{Z}} \sum_{n \in \mathbb{Z}} w(n)q(l - n)\tilde{q}(k - l) = \sum_{n \in \mathbb{Z}} w(n)\delta_{k - n, 0} = w(k), \quad (S.32) \]
i.e., $w = p * \tilde{q}$. Thus, the sequence $w$ satisfying Eq. (S.32) is unique and given by $w = p * \tilde{q}$.

Since $w = p * q$ satisfies $\sum_{k \in \mathbb{Z}} w(k) = 1$, there exists a sequence $\{w(k)\}_{k \in \mathbb{Z}}$ that satisfies Eq. (S.32), $w(k) \geq 0$ and $\sum_{k \in \mathbb{Z}} w(k) = 1$ if and only if
\[ p * \tilde{q} \geq 0. \quad (S.33) \]

Theorem 4 is obtained as a corollary of Theorem 7 and a theorem in [23] on the convertibility:

**Theorem 8** (Theorem 3 in [23]). A pure state $\psi$ is converted to a pure state $\phi$ by a covariant operation if and only if there exists a probability distribution on integers $\{w(k)\}_{k \in \mathbb{Z}}$ such that $p_\psi = \sum_{k \in \mathbb{Z}} w(k)Y_k p_\phi$.

**The properties of a-majorization $\succ_a$**

We first show that the binary relation $\succ_a$ is a preorder. For any probability distribution $p = \{p(n)\}_{n \in \mathbb{Z}}$, it holds $p \succ_a p$ since $p * \tilde{p} = \delta_0 \geq 0$. For probability distributions $p = \{p(n)\}_{n=0}^{\infty}$, $q = \{q(n)\}_{n=0}^{\infty}$ and $r = \{r(n)\}_{n=0}^{\infty}$ such that $p \succ_a q$ and $q \succ_a r$, we have
\[ \sum_{l \in \mathbb{Z}} p(l)\tilde{r}(k - l) = \sum_{l, n \in \mathbb{Z}} p(l)\tilde{r}(k - n)\delta_{n - l, 0} \quad (S.34) \]
\[ = \sum_{l, n \in \mathbb{Z}} p(l)\tilde{r}(k - n) \sum_{m \in \mathbb{Z}} q(n - m)\tilde{q}(m - l) \quad (S.35) \]
\[ = \sum_{m \in \mathbb{Z}} \left( \sum_{l \in \mathbb{Z}} p(l)\tilde{q}(m - l) \right) \left( \sum_{n \in \mathbb{Z}} q(n - m)\tilde{r}(k - n) \right) \geq 0 \quad (S.36) \]
for all $k \in \mathbb{Z}$, which implies that $p \succ_a r$ holds. Therefore, the binary relation $\succ_a$ is a preorder. It should be noted that the majorization relation $\succ$ is also a preorder.

We further show the following proposition:
**Proposition 9.** For probability distributions $p$ and $q$, $p \succ_{\lambda} q$ and $q \succ_{\lambda} p$ hold if and only if there exists a shift operator $\Upsilon_k$ with an integer $k \in \mathbb{Z}$ such that $p = \Upsilon_k q$.

This corresponds to the fact that $\lambda \succ \lambda'$ and $\lambda' \succ \lambda$ hold if and only if there exists a permutation matrix $P$ such that $\lambda = P\lambda'$ in ordinary majorization theory.

**Proof of Proposition 9.** Let us first show the claim for probability distributions $\lambda$. For probability distributions $\nu$ and $\omega$, they satisfy

\[ \rho \succ \omega \iff \rho = \Upsilon_k \omega, \quad k \in \mathbb{Z}, \]

or equivalently,

\[ p = \Upsilon_k q, \quad k := n_{\star}^{(q)} - n_{\star}^{(p)}. \] (S.48)
Properties of $\mathcal{F}_{\text{max}}$ and $\mathcal{F}_{\text{min}}$ for pure states

Let us prove the monotonicity of the variance under $\succ_{a}$. Let $p$ and $q$ be probability distributions such that $p \succ_{a} q$. Since $p = \sum_{k \in \mathbb{Z}} w(k) Y_k q$ for a probability distribution $w = p * q \geq 0$, we have

$$
\mu_p := \sum_{n \in \mathbb{Z}} n p(n) = \sum_{k \in \mathbb{Z}} n \sum_{k \in \mathbb{Z}} w(k) q(n - k)
= \sum_{k, n \in \mathbb{Z}} (k + (n - k)) w(k) q(n - k)
= \mu_w + \mu_q,
$$

(S.49)

(S.50)

(S.51)

Similarly, it holds that

$$
\text{Var}(p) = \sum_{n \in \mathbb{Z}} (n - \mu_p)^2 p(n)
= \sum_{k, n \in \mathbb{Z}} (k - \mu_w + (n - k) - \mu_q)^2 w(k) q(n - k)
= \sum_{k \in \mathbb{Z}} (k - \mu_w)^2 w(k) + \text{Var}(q)
\geq \text{Var}(q),
$$

(S.52)

(S.53)

(S.54)

(S.55)

where in the last line, we have used $w(k) \geq 0$ for all $k$. Of course, this monotonicity is expected from the fact that QFI monotonically decreases under a covariant operation and that QFI is four times the variance for pure states.

Equation (10) is a consequence of this monotonicity. To prove it, let us first show an easy but useful lemma:

**Lemma 10.** Let $\psi$ be a pure state. If $\mathcal{F}_{\text{max}}(\psi) < +\infty$, then for any $\lambda$ such that $4\lambda > \mathcal{F}_{\text{max}}(\psi)$, it holds $P_{\lambda} \succ_{a} P_{\psi}$. Similarly, if $\mathcal{F}_{\text{min}}(p) > 0$, then for any $\sigma$ such that $\mathcal{F}_{\text{min}}(\psi) > 4\sigma \geq 0$, it holds $p_{\psi} \succ_{a} P_{\sigma}$.

**Proof.** Fix any $\lambda \in \mathbb{R}$ such that $4\lambda > \mathcal{F}_{\text{max}}(\psi)$. From the definition of $\mathcal{F}_{\text{max}}(\psi)$, there exists a real parameter $\chi$ such that $4\lambda \geq 4\chi \geq \mathcal{F}_{\text{max}}(\psi)$ and $P_{\chi} \succ_{a} P_{\psi}$. From Eq. (S.24), $4\lambda \geq 4\chi$ implies $P_{\lambda} \succ_{a} P_{\chi}$. Therefore, we get $P_{\lambda} \succ_{a} P_{\psi}$.

Fix $\sigma$ such that $\mathcal{F}_{\text{min}}(\psi) > 4\sigma \geq 0$. Then there exists $\sigma'$ such that $\mathcal{F}_{\text{min}}(\psi) \geq 4\sigma' \geq 4\sigma$ and $p_{\psi} \succ_{a} P_{\sigma'}$. Again, from Eq. (S.24), we have $P_{\sigma'} \succ_{a} P_{\sigma}$, which implies $p_{\psi} \succ_{a} P_{\sigma}$.

Now note that $\mathcal{F}(\chi_{\lambda}) = 4\lambda$ holds for a pure state $\chi_{\lambda} = \sum_{n, n'=0}^{\infty} P_{\lambda}(n) P_{\lambda}(n') |n\rangle \langle n'|$. Therefore, $\mathcal{F}_{\text{max}}(\psi)$ and $\mathcal{F}_{\text{min}}(\psi)$ are the amount of coherence in $\psi$ that can be converted from and to the pure state $\chi_{\lambda}$ whose energy distribution is given by a Poisson distribution $P_{\lambda}$.

**Proposition 11** (Equation (10)). For any pure state $\psi$, it holds

$$
\mathcal{F}_{\text{max}}(\psi) \geq \mathcal{F}(\psi) \geq \mathcal{F}_{\text{min}}(\psi).
$$

(S.56)

**Proof.** If $\mathcal{F}_{\text{max}}(\psi) = +\infty$, then $\mathcal{F}_{\text{max}}(\psi) \geq \mathcal{F}(\psi)$ holds. Suppose that $\mathcal{F}_{\text{max}}(\psi) < +\infty$. From Lemma 10, $P_{\lambda} \succ_{a} P_{\psi}$ holds for any $\lambda$ such that $4\lambda > \mathcal{F}_{\text{max}}(\psi)$. From the monotonicity of the variance, we have $4\lambda \geq \mathcal{F}(\psi)$. Since $\lambda$ is arbitrary as long as $4\lambda \geq \mathcal{F}_{\text{max}}(\psi)$ is satisfied, we have $\mathcal{F}_{\text{max}}(\psi) \geq \mathcal{F}(\psi)$.

If $\mathcal{F}_{\text{min}}(\psi) = 0$, then $\mathcal{F}(\psi) \geq \mathcal{F}_{\text{min}}(\psi)$ trivially holds. Suppose that $\mathcal{F}_{\text{min}}(\psi) \neq 0$. From Lemma 10, $p_{\psi} \succ_{a} P_{\sigma}$ holds for any $\sigma$ such that $\mathcal{F}_{\text{min}}(\psi) > 4\sigma$. From the monotonicity of the variance, we have $\mathcal{F}(\psi) \geq 4\sigma$. Since $\sigma$ is arbitrary as long as $\mathcal{F}_{\text{min}}(\psi) > 4\sigma$ is satisfied, we have $\mathcal{F}(\psi) \geq \mathcal{F}_{\text{min}}(\psi)$.

Furthermore, it should be noted that when the energy distribution of a pure state $\psi$ is given by a Poisson distribution, it holds

$$
\mathcal{F}_{\text{max}}(\psi) = \mathcal{F}(\psi) = \mathcal{F}_{\text{min}}(\psi).
$$

(S.57)

We also prove the following proposition, which corresponds to Eqs. (14) and (15) in the one-shot regime:

**Proposition 12.** For any pure states $\psi$ and $\phi$, we have

1. If $\psi \succ_{\text{cov}} \phi$, then $\mathcal{F}_{\text{max}}(\psi) \geq \mathcal{F}_{\text{max}}(\phi)$ and $\mathcal{F}_{\text{min}}(\psi) \geq \mathcal{F}_{\text{min}}(\phi)$.
(2) If $\mathcal{F}_{\min}(\psi) > \mathcal{F}_{\max}(\phi)$, then $\psi \succeq \phi$.

Proof. (1): Assume that $\psi \succeq \phi$ holds. If $\mathcal{F}_{\max}(\psi) = +\infty$, then $\mathcal{F}_{\max}(\psi) \geq \mathcal{F}_{\max}(\phi)$ holds. Suppose that $\mathcal{F}_{\max}(\psi) < +\infty$. Let $\lambda$ be any real number such that $4\lambda > \mathcal{F}_{\max}(\psi)$. From Lemma 10, this means $P_\lambda \succ_a p_\psi$. Since $\succ_a$ is a preorder, it implies that $P_\lambda \succ_a p_\phi$ and therefore $4\lambda \geq \mathcal{F}_{\max}(\phi)$. Since $\lambda$ is an arbitrary real number such that $4\lambda > \mathcal{F}_{\max}(\psi)$, we have $\mathcal{F}_{\max}(\psi) \geq \mathcal{F}_{\max}(\phi)$.

If $\mathcal{F}_{\min}(\phi) = 0$, $\mathcal{F}_{\min}(\psi) \geq \mathcal{F}_{\min}(\phi)$ trivially holds since $\mathcal{F}_{\min}(\psi)$ is nonnegative for any pure state. Suppose that $\mathcal{F}_{\min}(\phi) > 0$. Let $\sigma$ be an arbitrary real number such that $\mathcal{F}_{\min}(\phi) > 4\sigma > 0$. From Lemma 10, $p_\phi \succ_a P_\sigma$. Since $\succ_a$ is preorder, we have $p_\phi \succ_a p_\sigma$ and therefore $\mathcal{F}_{\min}(\psi) \geq 4\sigma$. Since $\sigma$ is an arbitrary real number such that $\mathcal{F}_{\min}(\phi) > 4\sigma > 0$, we get $\mathcal{F}_{\min}(\psi) \geq \mathcal{F}_{\min}(\phi)$.

(2): Assume that pure states $\psi, \phi$ satisfy $\mathcal{F}_{\min}(\psi) > \mathcal{F}_{\max}(\phi)$. Fix a real number $\lambda$ such that $\mathcal{F}_{\min}(\psi) > 4\lambda > \mathcal{F}_{\max}(\phi)$. Lemma 10 shows that $p_\phi \succ_a P_\lambda$ and $P_\lambda \succ_a p_\phi$. Since $\succ_a$ is a preorder, we have $p_\psi \succ_a p_\phi$, or equivalently, $\psi \succeq \phi$. \qed

For comparison, here we summarize the properties of the max- and min-entropies without proof. For a review and details, see, e.g., [56] and the references therein. Hereafter, the base of the logarithm is set to 2. For a state $\rho$, the $\alpha$-Rényi entropy is defined by

$$S_\alpha(\rho) := \frac{1}{1-\alpha} \log \text{Tr}(\rho^\alpha).$$ (S.58)

The limits $\alpha \to 0$ and $\alpha \to +\infty$ yield the max-entropy $S_{\max}(\rho)$ and the min-entropy $S_{\min}(\rho)$, which are given by

$$S_{\max}(\rho) := \log (\text{rank}(\rho)), \quad S_{\min}(\rho) := -\log (\|\rho\|_\infty),$$ (S.59)

where $\text{rank}(\rho)$ and $\|\rho\|_\infty$ denote the rank of $\rho$ and the maximum eigenvalue of $\rho$, respectively. These entropies satisfy

$$S_{\max}(\rho) \geq S(\rho) \geq S_{\min}(\rho),$$ (S.60)

where $S(\rho) := -\text{Tr}(\rho \log \rho)$ is the von Neumann entropy. This corresponds to Eq. (S.56).

In entanglement theory, a maximally entangled state

$$|\Phi_d\rangle_{AB} = \frac{1}{\sqrt{d}} \sum_{i=1}^d |i\rangle_A |i\rangle_B,$$ (S.61)

is a reference state adopted in the literature, where $d$ denotes the dimension of the Hilbert spaces for each subsystem $A$ and $B$, while $\{|i\rangle_Z\}_{i=1}^d$ is an orthonormal basis for each subsystem $Z = A, B$. The reduced state is the maximally mixed state

$$\rho_d := \text{Tr}_B (\Phi_d) = \frac{1}{d} \mathbb{I}_d, \quad \Phi_d := |\Phi_d\rangle \langle \Phi_d|$$ (S.62)

where $\mathbb{I}_d$ denotes the identity operator. In this case, we have

$$S_{\max}(\rho_d) = S(\rho_d) = S_{\min}(\rho_d).$$ (S.63)

This corresponds to Eq. (S.57).

If a state $\rho$ is converted to another state $\sigma$ by LOCC, we denote $\rho \overset{\text{LOCC}}{\Rightarrow} \sigma$. An important theorem on the one-shot convertibility between pure states by LOCC is the following:

**Theorem 13.** Let $\psi_{AB}$ and $\phi_{AB}$ be bipartite pure states. Define the reduced states $\rho_A := \text{Tr}_B(\psi_{AB})$ and $\sigma_A := \text{Tr}(\phi_{AB})$. The following two hold:

(1) If $\psi_{AB} \overset{\text{LOCC}}{\Rightarrow} \phi_{AB}$, then $S_{\max}(\rho_A) \geq S_{\max}(\sigma_A)$ and $S_{\min}(\rho_A) \geq S_{\min}(\sigma_A)$.

(2) If $S_{\min}(\rho_A) \geq S_{\max}(\sigma_A)$, then $\psi_{AB} \overset{\text{LOCC}}{\Rightarrow} \phi_{AB}$.

This is the counterpart of Proposition 12.
\( F_{\text{max}} \) for general states

In the main text, we have defined

\[
F_{\text{max}}(\rho) := \inf_{\Psi_{\rho}, H_A} F_{\text{max}}(\Psi_{\rho}),
\]

where infimum is taken over the sets of all purifications \( \Psi_{\rho} \) of \( \rho \) and Hamiltonians \( H_A \) with integer eigenvalues of the auxiliary system \( A \) that is added to purify \( \rho \).

For any pure state \( \psi \), its purification is given by \( \psi \otimes \xi \) for some pure state \( \xi \). Since the partial trace is a covariant operation, we have \( p_{\psi \otimes \xi} \succ_a p_\psi \). By using Proposition 12, we get \( F_{\text{max}}(\psi \otimes \xi) \geq F_{\text{max}}(\psi) \). Therefore, Eq. (S.64) is consistent with Eq. (8).

**Proof of Eqs. (14) and (15)**

Equations (14) and (15) are obtained as a corollary of Theorem 1 and the following proposition:

**Proposition 14.** For any sequences of pure states \( \hat{\psi} = \{\psi_m\}_m \) and \( \hat{\phi} = \{\phi_m\}_m \), the followings hold:

(1) \( \hat{\psi} \succ^\text{cov} \hat{\phi} \implies C_{\text{cost}}(\hat{\psi}) \geq C_{\text{cost}}(\hat{\phi}), \quad C_{\text{dist}}(\hat{\psi}) \geq C_{\text{dist}}(\hat{\phi}). \)

(2) \( C_{\text{dist}}(\hat{\psi}) > C_{\text{cost}}(\hat{\phi}) \implies \hat{\psi} \succ^\text{cov} \hat{\phi}. \)

**Proof.** (1): For \( R := C_{\text{cost}}(\hat{\psi}) \) and any positive number \( \delta > 0 \), there exists \( \delta' \) such that \( \delta > \delta' \geq 0 \) and

\[
\hat{\phi}_{\text{coh}}(R + \delta') \succ^\text{cov} \hat{\psi}.
\]

Since \( \hat{\psi} \succ^\text{cov} \hat{\phi} \) holds from the assumption, we have \( \hat{\phi}_{\text{coh}}(R + \delta') \succ^\text{cov} \hat{\phi} \). Therefore,

\[
C_{\text{cost}}(\hat{\psi}) + \delta' \geq C_{\text{cost}}(\hat{\phi}).
\]

Since \( \delta > 0 \) is arbitrary and \( \delta > \delta' \), we have \( C_{\text{cost}}(\hat{\psi}) \geq C_{\text{cost}}(\hat{\phi}) \). In a similar way, \( C_{\text{dist}}(\hat{\psi}) \geq C_{\text{dist}}(\hat{\phi}) \) is proven.

(2): Fix \( R \) such that \( C_{\text{dist}}(\hat{\psi}) > R > C_{\text{cost}}(\hat{\phi}) \). There exists a real number \( R' \) such that \( C_{\text{dist}}(\hat{\psi}) \geq R' > R \) and

\[
\hat{\phi}_{\text{coh}}(R') \succ^\text{cov} \hat{\psi}.
\]

Since \( R > R' \) implies \( \hat{\phi}_{\text{coh}}(R') \succ^\text{cov} \hat{\psi} \), we get \( \hat{\psi} \succ^\text{cov} \hat{\phi} \).

**Facts on entanglement theory and spectral entropy rates**

We here provide results in entanglement theory in the literature without proof.

Let \( \psi_{AB} \) and \( \phi_{AB} \) be bipartite pure states. We define the density operators for the subsystem \( A \) as \( \rho_A := \text{Tr}\left(\psi_{AB}\right) \) and \( \sigma_A := \text{Tr}\left(\phi_{AB}\right) \). The entanglement entropy \( S_{\text{EE}} \) of \( \psi_{AB} \) is given by the von Neumann entropy \( S(\rho_A) \) of the reduced state \( \rho_A \), i.e.,

\[
S_{\text{EE}}(\psi_{AB}) := S(\rho_A) := -\text{Tr}\left(\rho_A \log \rho_A\right),
\]

where the base of the logarithm is 2. Consider sequences of i.i.d. pure states \( \tilde{\psi}_AB := \{\tilde{\psi}_{AB}\}_m \) and \( \tilde{\phi}_AB := \{\tilde{\phi}_{AB}^{\otimes \text{Rm}}\}_m \), where \( R > 0 \). We say that \( \tilde{\psi}_AB := \{\tilde{\psi}_{AB}\}_m \) can be asymptotically converted to \( \tilde{\phi}_AB(R) := \{\tilde{\phi}_{AB}^{\otimes \text{Rm}}\}_m \) if and only if there exists a sequence of local operations and classical communications (LOCC) \( \tilde{E} = \{\tilde{E}_m\}_m \) such that

\[
\lim_{m \to \infty} D\left(E_m(\tilde{\psi}_{AB}^{\otimes m}), \tilde{\phi}_{AB}^{\otimes \text{Rm}}\right) = 0.
\]
In this case, we denote $\hat{\psi}_{AB}^{\text{LOCC}} \succ \phi_{AB}(R)$. It is known [57] that the conversion from $\hat{\psi}_{AB}$ to $\phi_{AB}(R)$ by LOCC is possible if $R \leq S_{\text{EE}}(\psi_{AB})/S_{\text{EE}}(\phi_{AB})$ and impossible if $R > S_{\text{EE}}(\psi_{AB})/S_{\text{EE}}(\phi_{AB})$. In other words, pure states are interconvertible and the optimal rate is given by the ratio of the entanglement entropies in the i.i.d. regime.

To analyze the asymptotic convertibility in a more general setup, it is common to adopt a maximally entangled state as a reference. Let us first define the entanglement cost. For a given sequence of pure states $\psi = \{\psi_m\}_m$, we say that a rate $R$ is achievable in a dilution process if and only if there exists a sequence of nonnegative numbers $\{N_m\}_m$ such that $\hat{\Phi}(\{N_m\}) \succ \hat{\psi}$ and

$$\limsup_{m \to \infty} \frac{1}{m} \log N_m \leq R,$$

where we have defined $\hat{\Phi}(\{N_m\}) := \{\Phi_{N_m}\}_m$ for the maximally entangled state defined in Eq. (S.61). The entanglement cost of $\psi$ is defined by

$$E_{\text{cost}}(\psi) := \inf \{R \mid R \text{ is achievable in a dilution process}\}.$$  

(S.72)

In a similar way, we can define the distillable entanglement. We say that a rate $R$ is achievable in a distillation process if and only if there exists a sequence of nonnegative numbers $\{N_m\}_m$ such that $\hat{\psi}^{\text{LOCC}} \succ \hat{\Phi}(\{N_m\})$ and

$$\liminf_{m \to \infty} \frac{1}{m} \log N_m \geq R.$$

(S.73)

The distillable entanglement is defined as

$$E_{\text{dist}}(\hat{\psi}) := \sup \{R \mid R \text{ is achievable in a distillation process}\}.$$  

(S.74)

The spectral sup- and inf-entropy rates in the quantum case have been developed in different contexts, e.g., in [28, 29, 35, 36, 40, 58]. Here we provide one of the alternative but equivalent definitions, which is based on the smoothing technique [58]. For a given sequence of states $\hat{\rho} = \{\rho_m\}_m$, its spectral sup- and inf-entropy rates are defined by

$$\overline{S}(\hat{\rho}) := \lim_{\epsilon \to 0} \limsup_{m \to \infty} \frac{1}{m} S^\epsilon_{\max}(\rho_m), \quad \underline{S}(\hat{\rho}) := \lim_{\epsilon \to 0} \liminf_{m \to \infty} \frac{1}{m} S^\epsilon_{\min}(\rho_m),$$

where the smooth max- and min-entropies are defined by

$$S^\epsilon_{\max}(\rho) := \inf_{\sigma \in B^\epsilon(\rho)} S_{\max}(\sigma), \quad S^\epsilon_{\min}(\rho) := \sup_{\sigma \in B^\epsilon(\rho)} S_{\min}(\sigma)$$

(S.75)

for $B^\epsilon(\rho) := \{\sigma : \text{quantum states} | D(\sigma, \rho) \leq \epsilon\}$.

For a sequence of general pure states $\hat{\psi}_{AB} = \{\psi_{AB,m}\}_m$, let us define a sequence of reduced states by $\hat{\rho}_A = \{\rho_{A,m}\}_m$, where $\rho_{A,m} := \text{Tr}_B(\psi_{AB,m})$. It is shown [28, 29] that

$$E_{\text{cost}}(\hat{\psi}_{AB}) = \overline{S}(\hat{\rho}_A), \quad E_{\text{dist}}(\hat{\psi}_{AB}) = \underline{S}(\hat{\rho}_A).$$

(S.77)

For the convertibility between sequences of pure states $\hat{\psi}_{AB} = \{\psi_{AB,m}\}_m$ and $\hat{\phi}_{AB} = \{\phi_{AB,m}\}_m$, the following two hold [41]:

$$\hat{\psi}_{AB}^{\text{LOCC}} \succ \phi_{AB} \implies \overline{S}(\hat{\rho}_A) \geq \overline{S}(\hat{\sigma}_A), \quad \underline{S}(\hat{\rho}_A) \geq \underline{S}(\hat{\sigma}_A)$$

(S.78)

$$\overline{S}(\hat{\rho}_A) > \underline{S}(\hat{\sigma}_A) \implies \hat{\psi}_{AB}^{\text{LOCC}} \succ \phi_{AB},$$

(S.79)

where we have defined $\hat{\sigma}_A := \{\sigma_{A,m}\}_m$ and $\sigma_{A,m} := \text{Tr}_B(\phi_{AB,m})$. They are the counterparts of Eqs. (14) and (15) in entanglement theory.

In particular, for an i.i.d. sequence of pure states $\hat{\psi}_{AB} = \{\psi_{AB}^\otimes m\}_m$, the spectral entropy rates are equal to the entanglement entropy:

$$\overline{S}(\hat{\rho}_A) = S_{\text{EE}}(\psi_{AB}) = \overline{S}(\hat{\rho}_A).$$

(S.80)
Interconversion between $\hat{\phi}_{\text{coh}}(R)$ and $\hat{\chi}_\lambda$

We here show the following:

**Lemma 15.** A sequence $\hat{\phi}_{\text{coh}}(R)$ is interconverted to $\hat{\chi}_{R/4}$. That is, for any $\epsilon > 0$, $\hat{\phi}_{\text{coh}}(R) \succ \epsilon \hat{\chi}_{R/4}$ and $\hat{\chi}_{R/4} \succ \epsilon \hat{\phi}_{\text{coh}}(R)$.

Lemma 15 is proved based on the arguments in [26]. The following lemma connects the closeness of energy distributions and the convertibility of pure states.

**Lemma 16 ([26]).** Let $\psi$ and $\phi$ be pure states. There exists a covariant unitary operator $U$ such that

$$D(U\psi U^\dagger, \phi) \leq \sqrt{2d_{TV}(p_\psi, p_\phi)}.$$  \hfill (S.81)

Here, the total variation distance between two probability distributions is defined by

$$d_{TV}(p, q) := \frac{1}{2} \sum_{n \in \mathbb{Z}} |p(n) - q(n)|.$$ \hfill (S.82)

In the i.i.d. regime, the translated Poisson distribution plays an important role, which is defined as follows:

**Definition 17** (The translated Poisson distribution). For $\mu \in \mathbb{R}$ and $\sigma^2 \geq 0$, the translated Poisson distribution is defined by

$$TP_{\mu, \sigma^2}(n) := P_{\sigma^2+\gamma}(n-s) = \begin{cases} e^{-\sigma^2+\gamma} (\sigma^2+\gamma)^{n-s} (n-s)!^{-\gamma} & \text{(For } n = s, s+1, s+2, s+3, \cdots) \\ 0 & \text{(Otherwise)}, \end{cases}$$ \hfill (S.83)

where $s := |\mu - \sigma^2|$ is an integer and $\gamma := \mu - \sigma^2 - |\mu - \sigma^2|$ is a parameter satisfying $0 \leq \gamma < 1$. The mean and variance are given by $\mu$ and $\sigma^2 + \gamma$, respectively. Alternatively, the translated Poisson distribution is written as $TP_{\mu, \sigma^2} = Y_{|\mu-\sigma^2|} P_{\sigma^2+\gamma}$.

It is known that the sum of integer-valued random variables converges to the translated Poisson distribution [26, 59]. Let $\{Z_i\}_{i=1}^m$ be a set of independent random variables with mean $\mu_i := \mathbb{E}Z_i$ and variance $\sigma_i^2 := \mathbb{E}((Z_i - \mu_i)^2)$. Assume that its absolute third moment $\mathbb{E}|Z_i^3|$ is finite. Let $L(Z)$ denote the probability distribution of a random variable $Z$. We define

$$v_i := \min \left\{ \frac{1}{2}, 1 - d_{TV}(L(Z_i), L(Z_i + 1)) \right\},$$ \hfill (S.84)

$$\psi_i := \sigma_i^2 \mathbb{E}(Z_i(Z_i - 1)) + |\mu_i - \sigma_i^2| \mathbb{E}((Z_i - 1)(Z_i - 2)) + \mathbb{E}((Z_i)(Z_i - 1)(Z_i - 2)).$$ \hfill (S.85)

For the sum of the random variables $W := \sum_{i=1}^m X_i$ with mean $\tilde{\mu} := \mathbb{E}(W) = \sum_{i=1}^m \mu_i$ and variance $\tilde{\sigma}^2 := \mathbb{E}((W - \tilde{\mu})^2) = \sum_{i=1}^m \sigma_i^2$, the following theorem holds:

**Theorem 18** (Corollary 3.2 in [59], Theorem 7 in [26]). Suppose that the random variable $Z_i$ satisfies $\sigma_i^2 \geq a > 0$, $v_i \geq b > 0$ and $\sigma_i^{-2} \psi_i \leq c < \infty$ for any $1 \leq i \leq m$ with some parameters $a, b$ and $c$. Then

$$d_{TV}(L(W), TP_{\tilde{\mu}, \tilde{\sigma}^2}) \leq \frac{c}{\sqrt{mb - \frac{1}{2}}} + \frac{2}{ma}.$$ \hfill (S.86)

Applying this theorem to the energy distribution of $\phi^{\otimes[Rm]}_{\text{coh}}$, we get

$$\lim_{m \to \infty} d_{TV}(p_{\phi^{\otimes[Rm]}_{\text{coh}}}, TP_{\frac{1}{2}[Rm], \frac{1}{2}[Rm]}) = 0.$$ \hfill (S.87)

For Poisson distributions with different variance, the upper bound on the total variation distance is provided in the following theorem:
Theorem 19 (Equation (5) in Ref. [60], Equation (2.2) in Ref. [61], Lemma 8 in Ref. [26]).

\[ d_{TV}(P_{\sigma^2},P_{\sigma'^2}) \leq \min \left\{ x, \sqrt{\frac{2}{\pi}} \left( \sqrt{\sigma^2 + x} - \sigma \right) \right\}, \tag{S.88} \]

where \( x := |\sigma^2 - \sigma'^2| \).

Let us define \( s_m := \lfloor \frac{1}{2} Rm \rfloor \) and \( \gamma_m := \lfloor \frac{1}{4} Rm \rfloor - \lfloor \frac{1}{2} Rm \rfloor - \lfloor \frac{1}{2} Rm \rfloor - \lfloor \frac{1}{4} Rm \rfloor \). From Eq. (S.87) and Theorem 19, we have

\[ \begin{align*}
d_{TV} & \left( p_{\phi^\otimes[Rm]}, Y_{s_m} P_{\frac{1}{2} Rm} \right) \tag{S.89} \\
& \leq d_{TV} \left( p_{\phi^\otimes[Rm]}, TP_{\frac{1}{2}}[Rm], \frac{1}{4}[Rm] \right) + d_{TV} \left( TP_{\frac{1}{2}}[Rm], \frac{1}{4}[Rm], Y_{s_m} P_{\frac{1}{2} Rm} \right) \tag{S.90} \\
& = d_{TV} \left( p_{\phi^\otimes[Rm]}, TP_{\frac{1}{2}}[Rm], \frac{1}{4}[Rm] \right) + d_{TV} \left( P_{\frac{1}{4}}[Rm], \frac{1}{4}[Rm], Y_{s_m} P_{\frac{1}{2} Rm} \right) \tag{S.91} \\
& \to 0 \tag{S.92}
\end{align*} \]

as \( m \to \infty \).

Let us define \( m := Y_{s_m} P_{\frac{1}{2} Rm} \) and pure states \( \kappa_m := \sum_{n,n' \in \mathbb{Z}} q_m(n) q_m(n') |n\rangle \langle n'| \). Since \( P_{\frac{1}{4} Rm} \succ q_m \) and \( q_m \succ P_{\frac{1}{4} Rm} \) hold, there exist covariant channels \( \Lambda_m \) and \( \Lambda'_m \) such that \( \chi_{\frac{1}{4} Rm} = \Lambda_m(\kappa_m) \) and \( \kappa_m = \Lambda'_m(\chi_{\frac{1}{4} Rm}) \). On the other hand, according to Lemma 16, there exist covariant channels \( \Theta_m \) and \( \Theta'_m \) such that

\[ \begin{align*}
D \left( \Theta_m \left( \phi^\otimes[Rm] \right), \kappa_m \right) \leq \sqrt{2d_{TV} \left( p_{\phi^\otimes[Rm]}, Y_{s_m} P_{\frac{1}{2} Rm} \right)} \tag{S.93} \\
D \left( \Theta'_m \left( \kappa_m \right), \phi^\otimes[Rm] \right) \leq \sqrt{2d_{TV} \left( p_{\phi^\otimes[Rm]}, Y_{s_m} P_{\frac{1}{2} Rm} \right)} \tag{S.94}
\end{align*} \]

Defining \( \mathcal{E}_m := \Lambda_m \circ \Theta_m \) and \( \mathcal{E}'_m := \Theta'_m \circ \Lambda'_m \), we have

\[ \lim_{m \to \infty} D \left( \mathcal{E}_m \left( \phi^\otimes[Rm] \right), X_{\frac{1}{4} Rm} \right) = \lim_{m \to \infty} D \left( \phi^\otimes[Rm], \mathcal{E}'_m(\chi_{\frac{1}{4} Rm}) \right) = 0, \tag{S.95} \]

which concludes the proof of Lemma 15.

Proof of Lemma 5

Proof. Let \( \mathcal{E} \) be a covariant channel with respect to the Hamiltonian given by Eq. (3). From the covariant Stinespring dilation theorem [25, 62], there exists an ancillary system \( A \), a symmetric pure state \( \eta_A \) of \( A \), the Hamiltonian \( H_A \) and a covariant unitary operator \( U \) such that

\[ \mathcal{E} \left( \cdots \right) = \text{Tr}_A \left( U \left( \cdots \otimes \eta_A \right) U^\dagger \right). \tag{S.96} \]

In our setup, the Hamiltonian of the original system is assumed to be given by Eq. (3). In this case, the Hamiltonian \( H_A \) of the auxiliary system has integer eigenvalues. Furthermore, without loss of generality, it is possible to assume that \( \eta_A \) is an energy eigenstate with a vanishing eigenvalue of \( H_A \), i.e., \( H_A |\eta_A\rangle = 0 \).

For \( \chi_\lambda = |\lambda\rangle \langle \lambda| \) and \( |\lambda\rangle := \sum_{n=0}^{\infty} P_\lambda(n) |n\rangle \), we define \( \Phi := U (\chi_\lambda \otimes \eta_A) U^\dagger \). Since \( U \) is covariant and \( H_A |\eta_A\rangle = 0 \) holds, we have \( p_\Phi = P_\lambda \). In addition, \( \Phi \) is a purification of \( \mathcal{E}(\chi_\lambda) \), which concludes the proof of Lemma 5.

Lemma 5 shows that \( \mathcal{F}_\infty(p) \) for a general state \( p \) quantifies the minimum amount of coherence in \( \chi_\lambda \) required to generate \( p \).

Proof of Lemma 6

Instead of Lemma 6, we here prove a slightly improved lemma:
Lemma 20. Let \( \psi \) and \( \phi \) be pure states. If there exists a covariant channel \( \mathcal{E} \) such that \( \mathcal{E}(\psi) \approx_\epsilon \phi \) for \( 0 \leq \epsilon \leq 1 \), then there exists a pure state \( \psi' \) such that \( \psi' \in B_{\text{pure}}^{(\epsilon)}(\psi) \) and \( p_{\psi'} >_a p_\phi \) for \( f(\epsilon) := \sqrt{2\sqrt{1-(1-\epsilon)^2}} \).

In the proof Lemma 20, we use the following:

Lemma 21. Let \( \psi \) and \( \phi \) be arbitrary states. For a covariant channel \( \mathcal{E} \), if

\[
\epsilon \geq D(\mathcal{E}(\psi), \phi) \tag{S.97}
\]

for some \( 1 \geq \epsilon \geq 0 \), then there exists a probability distribution \( \{w(k)\}_{k \in \mathbb{Z}} \) such that

\[
d_{TV}(p_\psi, \sum_{k \in \mathbb{Z}} w(k) \Upsilon_k p_\phi) \leq \sqrt{1-(1-\epsilon)^2}. \tag{S.98}
\]

Proof. It is known \[23\] that any covariant quantum channel has a Kraus representation with Kraus operators \( \{K_{k,u}\} \) such that

\[
K_{k,u} := \sum_{n=\max(0,-k)}^{\infty} c_n^{(k,u)} |n-k\rangle \langle n| \quad (S.99)
\]

\[
= \sum_{n \in \mathbb{Z}} c_n^{(k,u)} |n-k\rangle \langle n|, \tag{S.100}
\]

where in the second line, for notational simplicity, we defined \( c_n^{(k,u)} = 0 \) if \( n < \max\{0,-k\} \). For the channel to be trace-preserving, the coefficients must satisfy

\[
\sum_{k,u} |c_n^{(k,u)}|^2 = 1 \tag{S.101}
\]

for all \( n \geq 0 \). Note that

\[
\sum_{k,u} K_{k,u}^\dagger |n-k\rangle \langle n-k| K_{k,u} = \sum_{k,u} |c_n^{(k,u)}|^2 |n\rangle \langle n| = |n\rangle \langle n|. \tag{S.102}
\]

For a given pure state \( \psi \), we define

\[
q^{(k,u)} := \|K_{k,u} |\psi\| \tag{S.103}
\]

For each \( (k,u) \) such that \( q^{(k,u)} \neq 0 \), we define a normalized pure state

\[
|\phi^{(k,u)} \rangle := \frac{1}{\sqrt{q^{(k,u)}}} K_{k,u} |\psi\rangle. \tag{S.104}
\]

The energy distributions for pure states are related as

\[
p_\psi(n) := \langle \psi | n \rangle \langle n | \psi \rangle \tag{S.105}
\]

\[
= \sum_{k,u} \langle \psi | K_{k,u}^\dagger |n-k\rangle \langle n-k| K_{k,u} |\psi\rangle \tag{S.106}
\]

\[
= \sum_{k,u} q^{(k,u)} \langle \phi^{(k,u)} | n-k \rangle \langle n-k | \phi^{(k,u)} \rangle \tag{S.107}
\]

\[
= \sum_{k,u} q^{(k,u)} p_{\phi^{(k,u)}}(n-k), \tag{S.108}
\]

or equivalently,

\[
p_\psi = \sum_{k,u} q^{(k,u)} \Upsilon_k p_{\phi^{(k,u)}} = \sum_k w_k \Upsilon_k p_{\phi^{(k,u)}}, \tag{S.109}
\]
where we have defined
\[ w(k) := \sum_u q^{(k,u)}. \]  

(S.110)

For this probability distribution \( \{w(k)\}_{k \in \mathbb{Z}} \), we have
\[
d_{\text{TV}} \left( p_\psi, \sum_k w(k) \Upsilon_k p_\phi \right) = d_{\text{TV}} \left( \sum_{k,u} q^{(k,u)} \Upsilon_k p_{\phi^{(k,u)}}, \sum_{k,u} q^{(k,u)} \Upsilon_k p_\phi \right) \]  
\[= \sum_{k,u} q^{(k,u)} d_{\text{TV}} \left( \Upsilon_k p_{\phi^{(k,u)}}, \Upsilon_k p_\phi \right) \]  
\[= \sum_{k,u} q^{(k,u)} d_{\text{TV}} \left( p_{\phi^{(k,u)}}, p_\phi \right) \]  
\[\leq \sqrt{\sum_{k,u} q^{(k,u)} d^2_{\text{TV}} \left( p_{\phi^{(k,u)}}, p_\phi \right)}. \]  

(S.111)

(S.112)

(S.113)

(S.114)

By using the Fuchs–van de Graaf inequalities, we have
\[
\epsilon \geq D(E(\psi), \phi) \]  
\[\geq 1 - \sqrt{F(E(\psi), \phi)} \]  
\[= 1 - \sqrt{\sum_{k,u} q^{(k,u)} F(\phi^{(k,u)}, \phi)} \]  
\[\geq 1 - \sqrt{1 - \sum_{k,u} q^{(k,u)} D^2(\phi^{(k,u)}, \phi)} \]  
\[\geq 1 - \sqrt{1 - \sum_{k,u} q^{(k,u)} d^2_{\text{TV}} \left( p_{\phi^{(k,u)}}, p_\phi \right)}, \]  
which implies that
\[ \sum_{k,u} q^{(k,u)} d^2_{\text{TV}} \left( p_{\phi^{(k,u)}}, p_\phi \right) \leq 1 - (1 - \epsilon)^2. \]  

(S.115)

(S.116)

(S.117)

(S.118)

(S.119)

Therefore, we finally get
\[
d_{\text{TV}} \left( p_\psi, \sum_k w(k) \Upsilon_k p_\phi \right) \leq \sqrt{1 - (1 - \epsilon)^2}. \]  

(S.120)

(S.121)

Proof of Lemma 20. From Lemma 21, there exists a probability distribution \( \{w(k)\}_{k \in \mathbb{Z}} \) such that
\[
d_{\text{TV}} \left( p_\psi, \sum_k w(k) \Upsilon_k p_\phi \right) \leq \sqrt{1 - (1 - \epsilon)^2}. \]  

(S.122)

Defining \( q := w * p_\phi \) and \( |\psi''\rangle := \sum_n q(n) |n\rangle \), from Lemma 16, there exists a covariant unitary operator \( U \) such that
\[ D(\psi, \psi') \leq \sqrt{2} d_{\text{TV}}(p_\psi, q) \leq \sqrt{2} \sqrt{1 - (1 - \epsilon)^2}, \quad \psi' := U \psi'' U^\dagger. \]  

(S.123)

Since \( q \succ_n p_\phi \) and \( p_{\psi'} \succ_n q \), we have \( p_{\psi'} \succ_n p_\phi \).

\[ \square \]

In the main text, we used a looser bound \( 2\epsilon^{1/4} \) instead of \( \sqrt{2} \sqrt{1 - (1 - \epsilon)^2} \) to simplify the notation.
Proof of Theorem 2

Theorem 2 can be proven in the same way as the first part of Theorem 1. For completeness, we here repeat the proof.

Proof of Theorem 2. To show $C_{\text{cost}}(\rho) = \mathcal{F}(\rho)$, let us define $C_{\text{cost}}(\rho) := \inf \{ R \mid \tilde{\phi}_{\text{coh}}(R) \triangleright_{\epsilon} \rho \}$. Defining $4\lambda'^{2} := C_{\text{cost}}(\rho)$, for any parameter $\delta > 0$, there exists a real number $\delta'$ such that $\delta > \delta' \geq 0$ and $\tilde{\phi}_{\text{coh}}(4(\lambda'^{2} + \delta')) \triangleright_{\epsilon/2} \rho$.

Since $\tilde{\chi}(\lambda'/2+\delta') \triangleright_{\epsilon}/2 \tilde{\phi}_{\text{coh}}(4(\lambda'/2 + \delta'))$, we have $\tilde{\chi}(\lambda'/2+\delta') \triangleright_{\epsilon} \rho$, where we have used Eq. (S.24). From Lemma 5, for all sufficiently large $m$, there exists a state $\sigma_m \in B_\epsilon(\rho_m)$ whose purification $\Phi_m$ satisfies $P_{\lambda'/2+\delta} \triangleright_{\epsilon} \rho_m$. Therefore, $4(\lambda'/2 + \delta)m \geq F_{\text{max}}(\rho_m)$ for sufficiently large $m$, which implies

$$C_{\text{cost}}(\rho) \geq \limsup_{m \to \infty} \frac{1}{m} F_{\text{max}}(\rho_m).$$

(S.124)

Since $\delta > 0$ is arbitrary, we have $C_{\text{cost}}(\rho) \geq \mathcal{F}(\rho)$ in the limit of $\epsilon \to +0$.

To show the opposite inequality, let us define $4\lambda'^{2} := F_{\text{max}}(\rho_m)$. For any $\delta > 0$, there exist $\delta'_{m}$, satisfying $\delta > \delta'_{m} \geq 0$, such that there exist a state $\sigma_m \in B_\epsilon(\rho_m)$ and its purification $\Phi_m$ satisfying $P_{\lambda'/2+\delta} \triangleright_{\epsilon} \rho_m$. Note that for all sufficiently large $m$, $m(\lambda'/2 + \delta) \geq \lambda'^{2}/2$ holds for $\lambda'^{2} := \limsup_{m \to \infty} \frac{1}{m} \lambda'^{2}$. Therefore, we get $P_{\lambda'/2+2\delta} \triangleright_{\epsilon} \rho_m$, where we have used $m\delta > \delta'_{m}$. Since $\tilde{\phi}_{\text{coh}}(4(\lambda'/2 + 2\delta)) \triangleright_{\epsilon/2} \tilde{\chi}(\lambda'/2+2\delta)$, we have $\tilde{\phi}_{\text{coh}}(4(\lambda'/2 + 2\delta)) \triangleright_{\epsilon/2} \Phi_m$. Therefore, $C_{\text{cost}}(\rho) \leq \limsup_{m \to \infty} \frac{1}{m} F_{\text{max}}(\rho_m) + 8\delta$.

(S.125)

Since $\delta > 0$ is arbitrary, as $\epsilon \to +0$, we have $C_{\text{cost}}(\rho) \leq \mathcal{F}(\rho)$, and therefore $C_{\text{cost}}(\rho) = \mathcal{F}(\rho).$
