Solving forward and inverse problems in a non-linear 3D PDE via an asymptotic expansion based approach

Dmitrii Chaikovskii† and Ye Zhang‡

Abstract. This paper is concerned with the usage of the asymptotic expansion method for efficiently solving forward and inverse problems in a non-linear singularly perturbed time-dependent reaction–diffusion–advection equation. By using the asymptotic expansion with the local coordinates in the transition layer region, we prove the existence and uniqueness of a smooth solution with a sharp transition layer for a three-dimensional PDE. Moreover, with the help of asymptotic expansion, a simplified model is derived for the corresponding inverse source problem, which is close to the original inverse problem over the entire region except for a narrow transition layer. We show that such simplification does not reduce the accuracy of the inversion result when the measurement data contains noise. Based on this simpler inversion model, an asymptotic expansion regularization algorithm is proposed for solving the inverse source problem in the three-dimensional case. Various numerical examples for both forward and inverse problems are given to show the efficiency of the proposed numerical approach.

Key words. Singular perturbed PDE, Reaction-diffusion-advection equation, Asymptotic expansion, Inverse source problem, Regularization, Convergence.

1. Introduction. In this paper, we aim to solve the following three-dimensional inverse source problem:

\[(IP)\): Given full noisy data \(\{u^\delta, u_x^\delta, u_y^\delta, u_z^\delta\}\) of \(\{u, u_x, u_y, u_z\}\) or partial noisy data \(u^\delta\) at the \(p \cdot q \cdot v\) location points \(\{x_i, y_j, z_k\}\) and at the time point \(t_0\), find the source function \(f(x, y, z)\) such that \((u, f)\) satisfies the following dimensionless nonlinear problem

\[
\begin{cases}
\begin{align*}
\mu \Delta u - \frac{\partial u}{\partial t} &= -u \left( \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \right) + f, \quad (x, y, z) \in \mathbb{R}^2, \quad z \in (-a, a) \equiv \Omega, \quad t \in (0, T] \equiv T, \\
u(x, y, z, t, \mu) &= u(x + L, y, z, t, \mu), \quad (x, y, z, t) \in \mathbb{R}^2 \times \bar{\Omega} \times \bar{T}, \\
u(x, y, -a, t, \mu) &= u^a(x, y), \quad (x, y, a, t, \mu) = u^a(x, y), \quad (x, y, t) \in \mathbb{R}^2 \times \bar{T}, \\
u(x, y, z, 0, \mu) &= u_{init}(x, y, z, \mu), \quad (x, y, z) \in \mathbb{R}^2 \times \bar{\Omega},
\end{align*}
\end{cases}
\]

where \(u(x, y, z, t)\) represents the dimensionless value (for example, of the temperature), \(\mu \ll 1\) is a small parameter (also called the diffusion coefficient), and \(f(x, y, z)\) is the source function. We assume that the function \(f(x, y, z)\) is \(L\)-periodic in the variable \(x\), \(M\)-periodic in the variable \(y\) and sufficiently smooth in the region \((x, y, z) : \mathbb{R}^2 \times \bar{\Omega} \ (\Omega \equiv (-a, a))\), that the
functions \( u^{-a}(x,y), u^a(x,y) \) are \( L \) and \( M \)-periodic in \( x,y \) respectively and sufficiently smooth in \( (x,y) \in \mathbb{R}^2 \), and that \( u_{\text{init}}(x,y,z,\mu) \) is a sufficiently smooth function in \( (x,y,z) : \mathbb{R}^3 \times \Omega \), \( L \)-periodic in \( x \), \( M \)-periodic in \( y \) and satisfy \( u_{\text{init}}(x,y,-a,\mu) = u^{-a}(x,y), u_{\text{init}}(x,y,a,\mu) = u^a(x,y) \).

This paper is focused on the solutions of problem (1.1) with a large gradient in a certain region. Such region is called the inner transition layer, the width of which is usually small compared to the width of the entire region. The presence of a small parameter makes the equation singularly perturbed. The reaction-diffusion-advection problems with inner transition layers are often used for mathematical modeling of density distribution of liquids or gases or temperature in the presence of spatial inhomogeneities [1, 2] or in nonlinear acoustics [3, 4, 5]. Such problems include, for example, studies of the temperature behavior in the near-surface layer of the ocean [6], description of the carrier wave functions in Si/Ge heterostructures [7], and propagation of an autowave front in a medium with barriers [8, 9]. Determination of existence conditions and stability of nonstationary solutions with large gradients is an important aspect for creating adequate models of processes with nonstationary distribution of fields of physical quantities. Analytical studies also make it possible to create effective numerical methods for solving equations with inner transition layers [11, 12, 13, 14, 15, 16, 28].

On the basis of a priori information obtained as a result of asymptotic analysis of problems with inner transitional layers, it is possible to develop efficient numerical algorithms for solving both direct and some classes of inverse problems [21, 23].

For the inverse source problem (IP) we use regularization methods since this problem is ill-posed (see [24]). The problem (IP) can be transformed to the following optimization problem with PDE constraints:

\[
\begin{align*}
\min_{f} \sum_{i=0}^{n} \sum_{j=0}^{m} & \left\{ \left[ u(x_i, y_j, z_k, t_0) - u^\delta(x_i, y_j, z_k, t_0) \right]^2 
+ \left[ \frac{\partial u}{\partial x}(x_i, y_j, z_k, t_0) - \frac{\partial u^\delta}{\partial x}(x_i, y_j, z_k, t_0) \right]^2 
+ \left[ \frac{\partial u}{\partial y}(x_i, y_j, z_k, t_0) - \frac{\partial u^\delta}{\partial y}(x_i, y_j, z_k, t_0) \right]^2 
+ \left[ \frac{\partial u}{\partial z}(x_i, y_j, z_k, t_0) - \frac{\partial u^\delta}{\partial z}(x_i, y_j, z_k, t_0) \right]^2 \right\} + \varepsilon \mathcal{R}(f),
\end{align*}
\]

where \( u \) solves the nonlinear PDE (1.1) with a given \( f \), \( \mathcal{R}(f) \) denotes the regularization term, and \( \varepsilon > 0 \) is the regularization parameter.

The main purpose of this work is to develop a new methodology for the efficient solution of direct and inverse problems in singularly perturbed PDEs in the three-dimensional case. For this purpose, we use the asymptotic method together with introducing of local coordinates to reduce the original PDE with a large derivative to a simpler equation of lower degree, obtaining quite accurate results. The one-dimensional formulation of the problem was considered in [7]. The introduction of local coordinates for the asymptotic solution was previously used in [25] for the two-dimensional reaction-diffusion-advection equation and in [26] for the two-dimensional reaction-diffusion problem. An asymptotic solution is constructed using the Vasil’eva algorithm [27]. It also should be noted that for the inverse problem a similar idea was used in [28] for the one-dimensional parameter identification problem in the singularly
perturbed reaction-diffusion equation, and in [29] for the one-dimensional inverse coefficient problem in the Burger-type equation.

This paper is organized as follows. In Section 2 we give the asymptotic analysis for the forward problem. The main results are presented in Section 3, while Section 4 presents the technical proofs of the main theoretical results. In Section 5, some experiments for the forward and inverse problems are described. Finally, concluding remarks are made in Section 6.

2. Asymptotic analysis. We investigate the solution of problem (1.1), which has the form of a moving front, that at each moment of time at \(-a \leq z \leq h(x,y,t)\) is close to the \(\varphi(-)(x,y,z)\), and for \(h(x,y,t) \leq z \leq a\) is close to the \(\varphi(+)(x,y,z)\), and sharply changes from \(\varphi(-)(x,y,z)\) to the values \(\varphi(+)(x,y,z)\) in a neighbourhood of the surface \(z = h(x,y,t)\). In this case, the solution to problem (1.1) has an inner transition layer in the vicinity of this surface.

First, we list all main assumptions that will be used throughout the paper.

Assumption 2.1. \(u^-(x,y) < 0, u^0(x,y) > 0\) and \(u^a(x,y) = 2\mu^2\) for all \((x,y) \in \mathbb{R}^2\).

Assumption 2.2. For any \((x,y,z) \in \mathbb{R}^2 \times \bar{\Omega}\)

\[
(\frac{z}{x-a-z,y-a-z})^2 > -2 \int_0^{a+z} f(x-a-z+s,y-a-z+s,-a+s) ds,
\]

\[
(\frac{z}{x+a-z,y+a-z})^2 > 2 \int_{z-a}^z f(x+a-z+s,y+a-z+s,a+s) ds.
\]

Assumption 2.3. \(-a < h_0(x,y,t) < a\) for any \((x,y,t) \in \mathbb{R}^2 \times \mathcal{T}\), where \(h_0\) is the zero approximation of \(h\), see (2.12), and \(\max_{(x,y) \in \mathbb{R}^2, t \in \mathcal{T}} \left(\frac{\partial h_0(x,y,t)}{\partial x} + \frac{\partial h_0(x,y,t)}{\partial y}\right) < 1\).

Assumption 2.4. \(u_{init}(x,y,z) = U_{n-1}(x,y,z,0) + \mathcal{O}(\mu^n)\), where the asymptotic solution \(U_{n-1}\) will be constructed later, see e.g. Theorem 3.1.

Under the Assumption 2.1 and 2.2, \(\varphi(-)(x,y,z)\) and \(\varphi(+)(x,y,z)\), which will be used for the construction of zero order asymptotic solution (cf. (2.23)), can be explicitly calculated from the reduced stationary equations (2.21) and (2.22) by using the method of characteristics:

\[
\begin{cases}
\varphi(-) = -\sqrt{(u^a(x-a-z,y-a-z))^2 - 2 \int_0^{a+z} f(x-a-z+s,y-a-z+s,-a+s) ds}, \\
\varphi(+) = \sqrt{(u^a(x+a-z,y+a-z))^2 - 2 \int_{z-a}^z f(x+a-z+s,y+a-z+s,a+s) ds}.
\end{cases}
\]

The surface \(z = h(x,y,t)\) at each moment of time divides the region \(\bar{\Omega}\) into two parts: \(\Omega(-) = \{z \in [-a; h(x,y,t)]\}\) and \(\Omega(+) = \{z \in [h(x,y,t); a]\}\).

Let us introduce the local coordinates \(r, l, m\) and write the equation of the normal to the surface \(h(l,m,t)\):

\[
\frac{x - l}{h_x(l,m,t)} = \frac{y - m}{h_y(l,m,t)} = \frac{z - h(l,m,t)}{-1}.
\]
The equation for the distance from the point with coordinates \((r, l, m)\) to the surface \(h(x, y, t)\) along the normal to it have the following form:

\[
r^2 = (x - l)^2 + (y - m)^2 + (z - h)^2 = (z - h)^2(1 + h^2_x + h^2_y).
\]

For a detailed description of the solution in the inner transition layer, in the vicinity of surface \(h(x, y, t)\), we proceed to extended variable:

(2.2) \[
\xi = \frac{r}{\mu},
\]

and to the local coordinates \((r, l, m)\) using the relations:

(2.3) \[
\begin{align*}
x &= l - \frac{r h_x}{\sqrt{1 + h^2_x + h^2_y}}, \\
y &= m - \frac{r h_y}{\sqrt{1 + h^2_x + h^2_y}} , \quad z = h(l, m, t) + \frac{r}{\sqrt{1 + h^2_x + h^2_y}}.
\end{align*}
\]

We assume that \(r > 0\) in the domain \(\mathbb{R}^2 \times \Omega^{(-)}\), \(r < 0\) in the domain \(\mathbb{R}^2 \times \Omega^{(+)},\) and notice that if \(z = h(l, m, t)\) then \(r = 0, \quad x = l, \quad y = m;\) the derivatives of the function \(h(l, m, t)\) in expression (2.3) are also taken for \(x = l\) and \(y = m.\)

The asymptotic approximation \(U(x, y, z, t, \mu)\) of the solution of the problem (1.1) will be constructed separately in each of the region \(\Omega^{(-)}\) and \(\Omega^{(+)};\)

(2.4) \[
U(x, y, z, t, \mu) = \begin{cases} 
U^{(-)}(x, y, z, t, \mu), & (x, y, z, t) \in \mathbb{R}^2 \times \Omega^{(-)} \times T, \\
U^{(+)}(x, y, z, t, \mu), & (x, y, z, t) \in \mathbb{R}^2 \times \Omega^{(+)} \times T,
\end{cases}
\]

as the sums of two terms

(2.5) \[
U^{(+)} = \bar{u}^{(+)}(x, y, z, \mu) + Q^{(+)}(\xi, l, m, h(l, m, t), t, \mu),
\]

where \(\bar{u}^{(+)}(x, y, z, t, \mu)\) – are the functions describing the outer layer, \(Q^{(+)}(\xi, l, m, h(l, m, t), t, \mu)\) – are the functions describing the inner transition layer.

Each term in (2.5) will be represented as an expansion in powers of the small parameter \(\mu:\)

(2.6) \[
\bar{u}^{(+)}(x, y, z, \mu) = \bar{u}_0^{(+)}(x, y, z) + \mu \bar{u}_1^{(+)}(x, y, z) + \ldots,
\]

(2.7) \[
Q^{(+)}(\xi, l, m, h, t, \mu) = Q_0^{(+)}(\xi, l, m, h, t) + \mu Q_1^{(+)}(\xi, l, m, h, t) + \ldots.
\]

We assume that \(z = h(x, y, t)\) – is the surface on which the solution \(u(x, y, z, t, \mu)\) to problem (1.1) at each time \(t\) takes on a value equal to the half-sum of the functions \(\bar{u}^{(-)}(x, y, h)\) and \(\bar{u}^{(+)}(x, y, h)\):

(2.8) \[
\phi(x, y, h(x, y, t), \mu) := \frac{1}{2} \left( \bar{u}^{(-)}(x, y, h(x, y, t), \mu) + \bar{u}^{(+)}(x, y, h(x, y, t), \mu) \right).
\]

For the zero-order approximation, it takes the form:

(2.9) \[
\phi_0(x, y, h(x, y, t)) := \frac{1}{2} \left( \varphi^{(-)}(x, y, h(x, y, t)) + \varphi^{(+)}(x, y, h(x, y, t)) \right).
\]
The functions $U^(-)(x, y, z, t, \mu)$ and $U^+(x, y, z, t, \mu)$ and their derivatives along the normal to the surface $z = h(x, y, t)$ will be matched continuously on the surface $h(x, y, t)$ at each moment of time $t$, i.e. the following two conditions hold.

\begin{align}
U^-(x, y, h(x, y, t), t, \mu) &= U^+(x, y, h(x, y, t), t, \mu) = \phi(x, y, h(x, y, t), \mu), \\
\frac{\partial U^-(x, y, h(x, y, t), t, \mu)}{\partial n} &= \frac{\partial U^+(x, y, h(x, y, t), t, \mu)}{\partial n},
\end{align}

where the function $\phi(x, y, h(x, y, t), \mu)$ is defined in (2.8).

The surface $z = h(x, y, t)$ will also be sought in the form of an expansion in powers of a small parameter:

\begin{equation}
(2.12) \quad h(x, y, t) = h_0(x, y, t) + \mu h_1(x, y, t) + \mu^2 h_2(x, y, t) + \ldots.
\end{equation}

Let us introduce a notation for the approximation of $h(x, y, t)$ with expansion terms up to order $n$:

\begin{equation}
(2.13) \quad \hat{h}_n(x, y, t) = \sum_{i=0}^{n} \mu^i h_i(x, y, t), \quad (x, y) \in \mathbb{R}^2, \quad t \in \bar{T}.
\end{equation}

We introduce the vectors $x = (x, y, z)^T$ and $r = (r, l, m)^T$, where $r = r(x, y, z, t), l = l(x, y, z, t), m = m(x, y, z, t)$ and $x, y, z$ are defined in (2.3).

The total differential of the vector $r$ is: $dr = \nabla_x r \, dx$. On the other hand, if we look at the inverse problem of determining the differential changes in our original coordinate system $(x, y, z)$ from the differential changes in the coordinate system $(r, l, m)$, we obtain: $dx = \nabla_r x \, dr$, whence follows $\nabla_x r = (\nabla_r x)^{-1}$; the expression has the following representation in matrix form:

\begin{equation}
(2.14) \quad \begin{pmatrix} \frac{\partial r}{\partial x} & \frac{\partial r}{\partial y} & \frac{\partial r}{\partial z} \\ \frac{\partial l}{\partial x} & \frac{\partial l}{\partial y} & \frac{\partial l}{\partial z} \\ \frac{\partial m}{\partial x} & \frac{\partial m}{\partial y} & \frac{\partial m}{\partial z} \end{pmatrix} = \begin{pmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial l} & \frac{\partial x}{\partial m} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial l} & \frac{\partial y}{\partial m} \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial l} & \frac{\partial z}{\partial m} \end{pmatrix}^{-1}.
\end{equation}

We rewrite the differential operators in the equation (1.1) in the variables $r, l, m, t$:

\begin{equation}
(2.15) \quad \nabla = \left\{ \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right\} = \left\{ \frac{\partial r}{\partial x} \frac{\partial}{\partial r} + \frac{\partial l}{\partial x} \frac{\partial}{\partial l} + \frac{\partial m}{\partial x} \frac{\partial}{\partial m}; \frac{\partial r}{\partial y} \frac{\partial}{\partial r} + \frac{\partial l}{\partial y} \frac{\partial}{\partial l} + \frac{\partial m}{\partial y} \frac{\partial}{\partial m}; \frac{\partial r}{\partial z} \frac{\partial}{\partial r} + \frac{\partial l}{\partial z} \frac{\partial}{\partial l} + \frac{\partial m}{\partial z} \frac{\partial}{\partial m} \right\},
\end{equation}

where the components of the operator $\nabla$ we find from the equations (2.3) and (2.14).
Differential operator $\Delta$ takes the form:

\begin{equation}
\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} = \frac{\partial}{\partial x} \frac{\partial}{\partial x} \frac{\partial}{\partial r} \frac{\partial}{\partial r} \left( \frac{\partial}{\partial x} \right) + \frac{\partial}{\partial x} \frac{\partial}{\partial l} \frac{\partial}{\partial l} \left( \frac{\partial}{\partial x} \right) + \frac{\partial}{\partial x} \frac{\partial}{\partial m} \frac{\partial}{\partial m} \left( \frac{\partial}{\partial x} \right),
\end{equation}

where the values for $\partial/\partial x, \partial/\partial y, \partial/\partial z$ are taken from (2.15).

Taking into account that

\begin{equation}
\xi = \frac{1}{\mu} \left( z - h(l, m, t) \right) \sqrt{1 + h^2_l + h^2_m},
\end{equation}

and obtaining expressions for $l, m$ from (2.3), rewrite the operator $\partial/\partial t$ in the variables $\xi, l, m, t$:

\begin{equation}
\frac{\partial}{\partial t} = \frac{\partial}{\partial t} - \frac{1}{\mu} \left( h_t \sqrt{1 + h^2_l + h^2_m} - \frac{r(h_l h_{lt} + h_m h_{mt})}{1 + h^2_l + h^2_m} \right) \frac{\partial}{\partial \xi}
- \left( h_t h_{lt} - \frac{r h_{lt}}{\sqrt{1 + h^2_l + h^2_m}} \right) \frac{\partial}{\partial l} - \left( h_t h_{mt} - \frac{r h_{mt}}{\sqrt{1 + h^2_l + h^2_m}} \right) \frac{\partial}{\partial m}.
\end{equation}

Substituting equations (2.5) in (1.1) and subtracting the outer part from the equation, and then moving to the variables $\xi, l, m, t$ using the equations (2.15),(2.16),(2.18) we obtain the equations for the transition layer functions $Q(\mp)(\xi, l, m, h(l, m, t), t, \mu)$:

\begin{equation}
\frac{1}{\mu} \left( \frac{\partial^2 Q(\mp)}{\partial \xi^2} + \frac{h_t(1 + h^2_l + h^2_m) - (h_l + h_m - 1) (\bar{u}(\mp)(l, m, h(l, m, t), \mu) + Q(\mp))}{\sqrt{1 + h^2_l + h^2_m}} \frac{\partial Q(\mp)}{\partial \xi} \right)
+ \sum_{i=0}^{\mu} \mu^i L_i [Q(\mp)] = 0,
\end{equation}

where $L_i$ represents differential operators of the first or second order in the variables $\xi, l, m, t$.

**2.1. Outer layer.** Let us find the outer functions of zero order by substitution the expansions (2.6) into the stationary equation:

\begin{equation}
\mu \Delta \bar{u} = -\bar{u} \left( \frac{\partial \bar{u}}{\partial x} + \frac{\partial \bar{u}}{\partial y} + \frac{\partial \bar{u}}{\partial z} \right) + f(x, y, z).
\end{equation}

Expanding the functions into the series in powers of a small parameter and equating the coefficients at the same powers $\mu$, we obtain partial differential equations of the first order for the functions $\bar{u}_i^{(\mp)}(x, y, z), i = 0, 1$. 
To be more precise, by equating the coefficients at $\mu^0$, we obtain the following equations:

\begin{equation}
\begin{cases}
\tilde{u}_0^{(-)} \left( \frac{\partial \tilde{u}_0^{(-)}}{\partial x} + \frac{\partial \tilde{u}_0^{(-)}}{\partial y} + \frac{\partial \tilde{u}_0^{(-)}}{\partial z} \right) = f(x, y, z), \\
\tilde{u}_0^{(-)}(x, y, -a) = u^{-a}(x, y), \quad \tilde{u}_0^{(-)}(x, y, z) = \tilde{u}_0^{(-)}(x + L, y, z) = \tilde{u}_0^{(-)}(x, y + M, z);
\end{cases}
\end{equation}

\begin{equation}
\begin{cases}
\tilde{u}_0^{(+)} \left( \frac{\partial \tilde{u}_0^{(+)}}{\partial x} + \frac{\partial \tilde{u}_0^{(+)}}{\partial y} + \frac{\partial \tilde{u}_0^{(+)}}{\partial z} \right) = f(x, y, z), \\
\tilde{u}_0^{(+)}(x, y, a) = u^a(x, y), \quad \tilde{u}_0^{(+)}(x, y, z) = \tilde{u}_0^{(+)}(x + L, y, z) = \tilde{u}_0^{(+)}(x, y + M, z).
\end{cases}
\end{equation}

According to Assumption 2.1, the equations (2.21) and (2.22) have solutions:

\begin{equation}
\tilde{u}_0(x, y, z) = \begin{cases}
\tilde{u}_0^{(-)}(x, y, z) = \varphi^{(-)}(x, y, z), \quad (x, y, z) \in \mathbb{R}^2 \times \bar{\Omega}^{(-)}, \\
\tilde{u}_0^{(+)}(x, y, z) = \varphi^{(+)}(x, y, z), \quad (x, y, z) \in \mathbb{R}^2 \times \bar{\Omega}^{(+)},
\end{cases}
\end{equation}

where $\varphi^{(\mp)}$ can be explicitly calculated, see (2.1).

First-order approximations of outer functions $\tilde{u}_1^{(\mp)}(x, y)$ are defined as solutions to problems

\begin{equation}
\begin{cases}
\frac{\partial \tilde{u}_1^{(\mp)}}{\partial x} + \frac{\partial \tilde{u}_1^{(\mp)}}{\partial y} + \frac{\partial \tilde{u}_1^{(\mp)}}{\partial z} + \tilde{u}_1^{(\mp)} P^{(\mp)}(x, y, z) = W^{(\mp)}(x, y, z), \\
\tilde{u}_1^{(-)}(x, y, -a) = 0, \quad \tilde{u}_1^{(+)}(x, y, a) = 0, \\
\tilde{u}_0^{(\pm)}(x, y, z) = \tilde{u}_0^{(\mp)}(x + L, y, z) = \tilde{u}_0^{(\mp)}(x, y + M, z),
\end{cases}
\end{equation}

where

$$P^{(\mp)}(x, y, z) = \frac{1}{\varphi^{(\mp)}} \left( \frac{\partial \varphi^{(\mp)}}{\partial x} + \frac{\partial \varphi^{(\mp)}}{\partial y} + \frac{\partial \varphi^{(\mp)}}{\partial z} \right), \quad W^{(\mp)}(x, y, z) = -\frac{\Delta \varphi^{(\mp)}}{\varphi^{(\mp)}}.$$

From (2.24) we obtain $\tilde{u}_1^{(\mp)}$ in its explicit form:

\begin{equation}
\begin{cases}
\tilde{u}_1^{(-)} = \int_{0}^{z+a} \exp \left( \int_{0}^{\zeta+a} P^{(-)}(x-z-a+s, y-z-a+s, -a+s) \, ds \right) W^{(-)}(x-z-a+c, y-z-a+c, -a+c) \, d\zeta, \\
\int_{0}^{z+a} \exp \left( \int_{0}^{\zeta+a} P^{(-)}(x-z-a+s, y-z-a+s, -a+s) \, ds \right) \, d\zeta,
\end{cases}
\end{equation}

\begin{equation}
\begin{cases}
\tilde{u}_1^{(+) = -\int_{z-a}^{0} \exp \left( \int_{0}^{\zeta-a} P^{(+)}(x-z+a+s, y-z+a+s, a+s) \, ds \right) W^{(+)}(x-z+a+c, y-z+a+c, a+c) \, d\zeta, \\
\int_{z-a}^{0} \exp \left( \int_{0}^{\zeta-a} P^{(+)}(x-z+a+s, y-z+a+s, a+s) \, ds \right) \, d\zeta.
\end{cases}
\end{equation}
2.2. Inner layer functions of zero order. We find inner transition layer functions of zero order \( Q_{0}^{(\mp)}(l, m, h_{0}, t) \) by substitution the series (2.6), (2.7) and (2.12) into equations (2.10) and (2.19), expanding all the terms of (2.19) in series in powers of \( \mu \) and equating the coefficients at \( \mu^{-1} \) in the equation (2.19) and at \( \mu^{0} \) in the equation (2.10) and taking into account additional condition for the decay of the transition functions at infinity, we obtain:

\[
\begin{equation}
\left\{ \begin{array}{l}
\frac{\partial^{2} Q_{0}^{(\mp)}}{\partial \xi^{2}} + \frac{h_{0l}(1 + h_{0l}^{2} + h_{0m}^{2}) + (1 - h_{0l} - h_{0m})(\varphi^{(\mp)}(l, m, h_{0}) + Q_{0}^{(\mp)})}{\sqrt{1 + h_{0l}^{2} + h_{0m}^{2}}} \frac{\partial Q_{0}^{(\mp)}}{\partial \xi} = 0; \\
\varphi^{(\mp)}(l, m, h_{0}) + Q_{0}^{(\mp)}(0, l, m, h_{0}, t) = \phi_{0}(l, m, h_{0}), \quad Q_{0}^{(\mp)}(\mp \infty, l, m, h_{0}, t) = 0.
\end{array} \right.
\end{equation}
\]

The function \( Q_{0}^{(-)} \) is defined for \( \xi \leq 0 \), while the functions \( Q_{0}^{(+)} \) is defined for \( \xi \geq 0 \).

In order to find the function \( h_{0}(l, m, t) \), introduce the auxiliary function:

\[
\tilde{u}(\xi, h_{0}(l, m, t)) = \begin{cases} 
\varphi^{(-)}(l, m, h_{0}) + Q_{0}^{(-)}(\xi, l, m, h_{0}, t), & \xi \leq 0, \\
\varphi^{(+)}(l, m, h_{0}) + Q_{0}^{(+)}(\xi, l, m, h_{0}, t), & \xi \geq 0.
\end{cases}
\]

Each of the equations (2.26), written in these notations, takes the form:

\[
\begin{equation}
\frac{\partial^{2} \tilde{u}}{\partial \xi^{2}} + \frac{h_{0l}(1 + h_{0l}^{2} + h_{0m}^{2}) + \tilde{u}(1 - h_{0l} - h_{0m})}{\sqrt{1 + h_{0l}^{2} + h_{0m}^{2}}} \frac{\partial \tilde{u}}{\partial \xi} = 0,
\end{equation}
\]

where the variables \( l, m, t \) and the function \( h(l, m, t) \) are parameters.

Denote by \( \frac{\partial \tilde{u}}{\partial \xi} = g(\tilde{u}), \frac{\partial^{2} \tilde{u}}{\partial \xi^{2}} = \frac{\partial g(\tilde{u})}{\partial \tilde{u}} g(\tilde{u}) \), (2.28) is transformed to

\[
\frac{\partial g(\tilde{u})}{\partial \tilde{u}} = -\frac{h_{0l}(1 + h_{0l}^{2} + h_{0m}^{2}) + \tilde{u}(h_{0l} + h_{0m} - 1)}{\sqrt{1 + h_{0l}^{2} + h_{0m}^{2}}},
\]

from which we can deduce that

\[
\begin{equation}
\frac{\partial \tilde{u}}{\partial \xi} = \begin{cases} 
\Phi^{(-)}(\xi, h_{0}(l, m, t)) = \int_{\varphi^{(-)}}^{\tilde{u}} \frac{-h_{0l}(1 + h_{0l}^{2} + h_{0m}^{2}) + \tilde{u}(h_{0l} + h_{0m} - 1)}{\sqrt{1 + h_{0l}^{2} + h_{0m}^{2}}} du, & \xi \leq 0, \\
\Phi^{(+)}(\xi, h_{0}(l, m, t)) = \int_{\varphi^{(+)}}^{\tilde{u}} \frac{-h_{0l}(1 + h_{0l}^{2} + h_{0m}^{2}) + \tilde{u}(h_{0l} + h_{0m} - 1)}{\sqrt{1 + h_{0l}^{2} + h_{0m}^{2}}} du, & \xi \geq 0.
\end{cases}
\end{equation}
\]

The derivative along the normal to the surface \( h(x, y, t) \) with respect to the variables \( x, y, z \) takes the form:

\[
\frac{\partial}{\partial n} = (\mathbf{n}, \nabla) = -\frac{h_{x}}{\sqrt{1 + h_{x}^{2} + h_{y}^{2}}} \frac{\partial}{\partial x} - \frac{h_{y}}{\sqrt{1 + h_{x}^{2} + h_{y}^{2}}} \frac{\partial}{\partial y} + \frac{1}{\sqrt{1 + h_{x}^{2} + h_{y}^{2}}} \frac{\partial}{\partial z},
\]

where \( \mathbf{n} = (h_{x}, h_{y}, 1) \) is the normal vector to the surface.
where values for the vector $\mathbf{n}$ are obtained from (2.3). With respect to the variables $\xi, l, m, t$, the derivative (2.30) has the form:

\[
\frac{\partial}{\partial n} = \frac{\partial}{\partial r} = \frac{1}{\mu} \frac{\partial}{\partial \xi}.
\]

Taking into account expansions (2.5)–(2.12) and (2.31), equating the coefficients at $\mu^{-1}$ in (2.11), we obtain (taking into account that at $\xi = 0$ we have $x = l, y = m$ and $z = h_0(x, y, t)$):

\[
\Phi^-(0, h_0(x, y, t)) - \Phi^+(0, h_0(x, y, t)) = 0.
\]

From (2.29) and (2.32) follows:

\[
\int \varphi^+(x,y,h_0(x,y,t)) \varphi^-(x,y,h_0(x,y,t)) - h_0 t \left( 1 + h_0^2 x + h_0^2 y \right) + \tilde{u} \left( h_0 x + h_0 y - 1 \right) \sqrt{1 + h_0^2 x + h_0^2 y} \, du = 0.
\]

The equation, which determines the zero approximation of the surface $h_0(x, y, t)$, takes the form:

\[
h_0 t \left( 1 + h_0^2 x + h_0^2 y \right) = \frac{1}{2} \left( h_0 x + h_0 y - 1 \right) \left( \varphi^+(x, y, h_0) + \varphi^-(x, y, h_0) \right),
\]

with additional boundary condition $h_0(x, y, 0) = h_0^* \in \tilde{\Omega}$ and periodic conditions on axes $x$ and $y$. By virtue of Assumption 2.2 and 2.3, equation (2.33) has a solution inside of the region $\Omega$ for any $(x, y, t) \in \mathbb{R}^3$.

We solve equations (2.29), and, with (2.33), the functions $Q_0^\pm(\xi, l, m, h_0, t)$ are given by the expressions in which $h_0(x, y, t)$ is a parameter:

\[
Q_0^\pm(\xi, l, m, h_0, t) = \frac{2P^\pm(x, y, h_0)}{\exp \left( -\xi P^\pm(x,y,h_0)(1-h_0x-h_0y) \right) + 1},
\]

where

\[
P^-(x, y, h_0) = \frac{1}{2} \left( \varphi^+(x, y, h_0) - \varphi^-(x, y, h_0) \right),
\]
\[
P^+(x, y, h_0) = \frac{1}{2} \left( \varphi^-(x, y, h_0) - \varphi^+(x, y, h_0) \right).
\]

Transition layer functions $Q_0^\pm(\xi, l, m, h_0, t)$ are exponentially decreasing with $\xi \to \mp \infty$ and satisfy the exponential estimates [30, 31]:

\[
Ce^{\xi} \leq |Q_0^-(\xi, l, m, h_0, t)| \leq \tilde{C}e^{\xi}, \quad \xi \leq 0, \quad t \in \tilde{T},
\]
\[
Ce^{-\xi} \leq |Q_0^+(\xi, l, m, h_0, t)| \leq \tilde{C}e^{-\xi}, \quad \xi \geq 0, \quad t \in \tilde{T},
\]
where $C, \bar{C}$ and $\kappa, \tilde{\kappa}$ – are four positive constants independent of $\xi, l, m, t$, and precisely,

\[
C := \frac{1}{2} \inf_{t \in T} \phi^+(x, y, h_0) - \phi^-(x, y, h_0),
\]

\[
\bar{C} := \frac{1}{2} \sup_{t \in T} \phi^+(x, y, h_0) - \phi^-(x, y, h_0).
\]

From the boundary conditions of (2.26) we deduce that

\[
|Q_0^{(+)}(0, x, y, h_0, t)| = |\phi_0(x, y, h_0) - \phi^+(x, y, h_0)| > \frac{1}{2} (u^a(x, y) - u^{-a}(x, y)) > \mu^2
\]

and $|Q_0^{(+)}(\xi, l, m, h_0, t)| \to 0$ for $\xi \to \mp \infty$. Since $\mu > 0$ is a constant, $|Q_0^{(+)}(\xi, l, m, h_0, t)|$ is a decreasing function and $\xi = \frac{1}{\sqrt{\bar{n}}} \sqrt{1 + h_l^2 + h_m^2 (H^{(+)}(l, m, t) - h(l, m, t))}$, then there exist such $H^{(+)}(l, m, t)$ that at the intervals $[-a, H^{(+)}(l, m, t)]$ and $[H^{(+)}(l, m, t), a]$ we have $|Q_0^{(+)}(\xi, l, m, h_0, t)| \leq \mu^2$ for every $l, m, t$, and at $z = H^{(\mp)}$ we have:

\[
(2.37) \quad |Q_0^{(-)}(\xi(H^{(-)}), l, m, H^{(-)}, t)| = \mu^2, \quad |Q_0^{(+)}(\xi(H^{(+)}, l, m, H^{(+)}, t)| = \mu^2.
\]

We denote the width of transition layer as

\[
\Delta h = \max_{(x, y) \in \mathbb{R}^2} \left( H^{(+)}(x, y, t) - H^{(-)}(x, y, t) \right),
\]

and from equations (2.35)-(2.36) for $z = H^{(\mp)}$ follows that:

\[
(2.38) \quad C e^{-\frac{\kappa}{2} \sqrt{1 + h_l^2 + h_m^2} \Delta h} \leq \mu^2 \leq \bar{C} e^{-\frac{\tilde{\kappa}}{2} \sqrt{1 + h_l^2 + h_m^2} \Delta h},
\]

from where the width of the inner transition layer $\Delta h$ can be estimated as:

\[
(2.39) \quad \frac{2\mu}{\kappa \sqrt{1 + h_l^2 + h_m^2}} \ln C \mu^2 \leq \Delta h \leq \frac{2\mu}{\tilde{\kappa} \sqrt{1 + h_l^2 + h_m^2}} \ln \bar{C} \mu^2, \text{ i.e. } \Delta h \sim \mu |\ln \mu|.
\]

2.3. Inner layer functions of the first order. Equations for first-order transition layer functions $Q_1^{(\mp)}(\xi, l, m, h_1, t)$ we obtain by equating the terms containing $\mu^0$ in the equation (2.19):

\[
(2.40) \quad \frac{\partial^2 Q_1^{(\mp)}}{\partial \xi^2} + \frac{\partial}{\partial \xi} \left( Q_1^{(\mp)} h_{0l} (h_{0l}^2 + h_{0m}^2 + 1) + \bar{u}(1 - h_{0l} - h_{0m}) \right)
\]

\[
= r_1^{(\mp)}(\xi, l, m, t) h_{1l} + r_2^{(\mp)}(\xi, l, m, t) h_{1m} + r_3^{(\mp)}(\xi, l, m, t) h_{1l} + r_4^{(\mp)}(\xi, l, m, t) h_{1m} + r_5^{(\mp)}(\xi, l, m, t)
\]

\[
:= f_1^{(\mp)}(\xi, l, m, t),
\]
where $r_1^{(+)}(\xi, l, m, t) - r_5^{(+)}(\xi, l, m, t)$ are known functions, and particularly, $r_4^{(+)}(\xi, l, m, t) = \frac{\partial Q_0^{(+)}(\xi, l, m, h_0, t)}{\partial \xi} \sqrt{1 + h_0^2 + h_0^2}$. The derivatives of the function $h_1(l, m, t)$ are taken for $l = x$ and $m = y$. Equation (2.10) in the order $\mu^1$ imply the boundary conditions

$$Q_1^{(+)}(0, l, m, \hat{h}_1, t) = \frac{1}{2} \left( \bar{u}_1^{(+)}(l, m, h_0) - \bar{u}_1^{(+)}(l, m, h_0) \right) := p_1^{(+)}(l, m, h_0).$$

We also add conditions at infinity

$$Q_1^{(+)}(\mp \infty, l, m, \hat{h}_1, t) = 0.$$ 

Solutions to problems (2.40)-(2.42) can be written explicitly:

$$Q_1^{(+)}(\xi, l, m, \hat{h}_1, t) = J^{(+)}(\xi, h_0) \left( p_1^{(+)}(l, m, h_0) \right) + \int_0^\xi ds \frac{ds}{J^{(+)}(s, h_0)} \int_{\mp \infty} f_1^{(+)}(\eta, l, m, t)d\eta ds,$$

where $J^{(+)}(\xi, h_0) = (\Phi^{(+)}(0, h_0))^{-1} \Phi^{(+)}(\xi, h_0)$.

It can be clearly shown that $Q_1^{(+)}(\xi, l, m, \hat{h}_1, t)$ satisfy exponential estimates (2.35) and (2.36). From (2.43) we find:

$$\frac{\partial Q_1^{(+)}(0, x, y, \hat{h}_1, t)}{\partial \xi} = p_1^{(+)}(x, y, h_0) \left( -h_0 \sqrt{1 + h_0^2 + h_0^2} \right)$$

$$+ \phi(x, y, h_0) \left( h_0 x + h_0 y - 1 \right) \sqrt{1 + h_0^2 + h_0^2} \right) - \int_0^{\mp \infty} f_1^{(+)}(\eta, x, y, t)d\eta.$$

From the first order $C^1$-matching condition (2.11), taking in account expansions (2.30) and (2.31), we obtain:

$$h_1(x, y, t) \left( \frac{\partial^2 Q_0^{(-)}(\xi, h_0)}{\partial \xi \partial h_0} - \frac{\partial^2 Q_0^{(+)}(\xi, h_0)}{\partial \xi \partial h_0} \right) + \frac{\partial Q_1^{(-)}(\xi, h_0)}{\partial \xi} - \frac{\partial Q_1^{(+)}(\xi, h_0)}{\partial \xi}$$

$$+ h_0 \left( \frac{\partial^2 \varphi^{(-)}(\eta, h_0)}{\partial y \partial \eta} - \frac{\partial^2 \varphi^{(-)}(\eta, h_0)}{\partial y \partial \eta} \right) + h_0 x \left( \frac{\partial \varphi^{(-)}(\eta, h_0)}{\partial x} - \frac{\partial \varphi^{(-)}(\eta, h_0)}{\partial x} \right) + \left( \frac{\partial \varphi^{(-)}(\eta, h_0)}{\partial \eta} - \frac{\partial \varphi^{(-)}(\eta, h_0)}{\partial \eta} \right) = 0.$$ 

From (2.40), (2.44), (2.45) we derive the equation that determines $h_1(x, y, t)$:

$$h_1 \left( \varphi^{(+)} - \varphi^{(-)} \right) \sqrt{1 + h_0^2 + h_0^2} = h_1 x V_1(x, y, t) + h_1 y V_2(x, y, t) + h_1 V_3(x, y, t) + V_4(x, y, t),$$

$$h_1(x, y, t) = h_1(x + L, y, t) = h_1(x, y + M, t), \quad h_1(x, y, 0) = 0,$$
where $V_1(x,y,t) - V_4(x,y,t)$ are known functions.

The problem for the function $h_1(x,y,t)$ is solvable due to the fact that the coefficient at the term $h_{1t}$ in equation (2.46) is positive.

In a similar way to (2.24)-(2.46), it is possible obtain asymptotic approximation terms up to $n$ order.

3. Main results. Above all, we summarize notations and abbreviations which will be frequently used in this section in Table 1.

Table 1: Notations and references to their definitions.

Below we present the main results of this paper, which are based on the results of the asymptotic analysis from Section 2.
Theorem 3.1. Suppose that functions \( f(x, y, z), u^{-a}(x, y), u^a(x, y), u_{init}(x, y, z) \) are sufficiently smooth, \( x \) and \( y \)-periodic, and \( \mu \ll 1 \). Then, under Assumptions 2.1–2.4, the boundary-value problem (1.1) has a unique smooth solution with an inner transition layer. In addition, the \( n \)-order asymptotic solution \( U_n(x, y, z, t, \mu) \) has the following representation:

\[
U_n = \begin{cases} 
U_n^{(-)} = \sum_{i=0}^{n} \mu^i \left( \tilde{u}_i^{(-)}(x, y, z) + Q_i^{(-)}(\xi, l, m, \tilde{h}, t) \right), \quad (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega}^{(-)} \times \tilde{T}, \\
U_n^{(+)} = \sum_{i=0}^{n} \mu^i \left( \tilde{u}_i^{(+)}(x, y, z) + Q_i^{(+)}(\xi, l, m, \tilde{h}, t) \right), \quad (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega}^{(+)} \times \tilde{T},
\end{cases}
\]

where \( \xi_i = (z - \hat{h}_i) \sqrt{1 + (\hat{h}_i)^2 + (\hat{h}_i)^2/\mu} \).

Moreover, the following asymptotic estimates hold:

\[
\forall (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega} \times \tilde{T}: \ |u(x, y, z, t) - U_n(x, y, z, t, \mu)| = O(\mu^{n+1}),
\]

\[
\forall (x, y, t) \in \mathbb{R}^2 \times \tilde{T}: \ |h(x, y, t) - \hat{h}_n(x, y, t)| = O(\mu^{n+1}),
\]

\[
\forall (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega} \setminus \{\tilde{h}_n(x, y, t)\} \times \tilde{T}: \ \left| \frac{\partial u(x, y, z, t)}{\partial n} - \frac{\partial U_n(x, y, z, t, \mu)}{\partial n} \right| = O(\mu^n).
\]

Corollary 3.2. (Zeroth approximation) Under the assumptions of Theorem 3.1, the zero-order asymptotic solution \( U_0 \) has the following representation:

\[
U_0(x, y, z, t) = \begin{cases} 
\varphi^{(-)}(x, y, z) + Q_0^{(-)}(\xi_0, l, m, h_0(l, m, t), t), \quad (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega}^{(-)} \times \tilde{T}, \\
\varphi^{(+)}(x, y, z) + Q_0^{(+)}(\xi_0, l, m, h_0(l, m, t), t), \quad (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega}^{(+)} \times \tilde{T},
\end{cases}
\]

where \( \xi_0 = (z - h_0) \sqrt{1 + (h_0)^2 + (h_0)^2/\mu} \). Moreover, the following holds:

\[
\forall (x, y, z, t) \in \mathbb{R}^2 \times \tilde{\Omega} \times \tilde{T}: \ |u(x, y, z, t) - U_0(x, y, z, t)| = O(\mu),
\]

\[
\forall t \in \tilde{T}: \ |h(x, y, t) - h_0(x, y, t)| = O(\mu).
\]

Furthermore, outside the narrow region \((h_0(x, y, t) - \Delta h/2, h_0(x, y, t) + \Delta h/2)\) with \( \Delta h \sim \mu|\ln \mu| \), there exists a constant \( C \) independent of \( x, y, z, t, \mu \) such that the following inequalities hold:

\[
|u(x, y, z, t) - \varphi^{(-)}(x, y, z)| \leq C \mu, \quad (x, y, z, t) \in \mathbb{R}^2 \times [-a, h_0(x, y, t) - \Delta h/2] \times \tilde{T},
\]

\[
|u(x, y, z, t) - \varphi^{(+)}(x, y, z)| \leq C \mu, \quad (x, y, z, t) \in \mathbb{R}^2 \times [h_0(x, y, t) + \Delta h/2, a] \times \tilde{T}.
\]
\[
\frac{\partial u(x, y, z, t)}{\partial n} - \frac{\partial \varphi^-(x, y, z)}{\partial n} \leq C\mu, \quad (x, y, z, t) \in \mathbb{R}^2 \times [-a, h_0(x, y, t) - \Delta h/2] \times \mathcal{T},
\]

\[
\frac{\partial u(x, y, z, t)}{\partial n} - \frac{\partial \varphi^+(x, y, z)}{\partial n} \leq C\mu, \quad (x, y, z, t) \in \mathbb{R}^2 \times [h_0(x, y, t) + \Delta h/2, a] \times \mathcal{T}.
\]

Corollary 3.2 follows directly from Theorem 3.1. Inequalities (3.10)–(3.11) in Corollary 3.2 can be obtained by taking into account the fact that the transition-layer functions are decreasing functions with respect to the \(\xi\) and are sufficiently small at the boundaries of the narrow region \((h_0(x, y, t) - \Delta h/2, h_0(x, y, t) + \Delta h/2)\), i.e. equation (2.37).

From Corollary 3.2, it follows that the solution can be approximated by outer functions of zero order everywhere, except for a thin transition layer. In view of this, we construct the approximate source function \(f\) by using only the outer functions of zero order, which can reduce the computational cost significantly but keep the accuracy of the result in case of a relatively high noise level and small size \(\mu\). To do this, suppose we have the deterministic noise model

\[
\max_{i,j,k} \left( |u(x_i, y_j, z_k, t_0) - u^\delta_{i,j,k}|, |u_x(x_i, y_j, z_k, t_0) - (u_x)^\delta_{i,j,k}|, \right.
|u_y(x_i, y_j, z_k, t_0) - (u_y)^\delta_{i,j,k}|, |u_z(x_i, y_j, z_k, t_0) - (u_z)^\delta_{i,j,k}| \leq \delta
\]

between the noisy data \(\{u^\delta_{i,j,k}, (u_x)^\delta_{i,j,k}, (u_y)^\delta_{i,j,k}, (u_z)^\delta_{i,j,k}\}\) and the corresponding exact quantities \(\{u(x_i, y_j, z_k, t_0), u_y(x_i, y_j, z_k, t_0), u_x(x_i, y_j, z_k, t_0), u_z(x_i, y_j, z_k, t_0)\}\) at time \(t_0\) and at grid points \(X_p := \{x_0 < x_1 < \cdots < x_p\}, Y_q := \{y_0 < y_1 < \cdots < y_q\}\) and \(Z_v := \{-a = y_0 < y_1 < \cdots < y_v = a\}\), with maximum mesh sizes in each direction: \(d_1 := \max_{i \in \{0, \ldots, p-1\}} \{x_{i+1} - x_i\},\)

\(d_2 := \max_{j \in \{0, \ldots, q-1\}} \{y_{j+1} - y_j\}\) and \(d_3 := \max_{k \in \{0, \ldots, v-1\}} \{z_{k+1} - z_k\}\).

To study the convergence, we define the pre-approximated source function \(f_0\)

\[
f_0(x, y, z) = u(x, y, z, t_0) \left( \frac{\partial u(x, y, z, t_0)}{\partial x} + \frac{\partial u(x, y, z, t_0)}{\partial y} + \frac{\partial u(x, y, z, t_0)}{\partial z} \right).
\]

**Proposition 3.3.** Let \(f^*\) be the exact source function, satisfying the original governing equation (1.1). Under Assumption 2.2, there exists a constant \(C_1\) independent of \(x, y, \mu\) such that, for any \(p \in (0, +\infty)\),

\[
\| f^* - f_0 \|_{L^p(\mathbb{R}^2 \times \Omega)} \leq C_1 \mu \| \ln \mu \|.
\]

According to Corollary 3.2, we can exclude data values \(\{u^\delta_{i,j,k}\}\) belonging to the inner transition layer, and use only nodes from the two regions \([-a, h_0(x, y, t) - \Delta h/2]\) and \([h_0(x, y, t) + \Delta h/2, a]\) with node indices \(k \in K\), where \(K := \{0, \ldots, v^(-), v^(+), \ldots, v\}\). We also introduce notations for the left region, \(\Omega^l \equiv [-a, -a + d_3 v^(-)]\), and for the right region, \(\Omega^r \equiv [-a + d_3 v^(+), a]\).
We restore the source function \( f^\delta(x, y, z) \) by using the following nonlinear formula.

\[
(3.15) \quad f^\delta = u^\delta(x, y, z, t_0) \left( \frac{\partial u^\delta(x, y, z, t_0)}{\partial x} + \frac{\partial u^\delta(x, y, z, t_0)}{\partial y} + \frac{\partial u^\delta(x, y, z, t_0)}{\partial z} \right).
\]

In case we know only the measurements \( u^\delta_{i,j,k}, (u_x)^\delta_{i,j,k}, (u_y)^\delta_{i,j,k}, (u_z)^\delta_{i,j,k} \) in (3.15) to the functions \( \{u^\varepsilon, \frac{\partial u^\varepsilon}{\partial x}, \frac{\partial u^\varepsilon}{\partial y}, \frac{\partial u^\varepsilon}{\partial z}\} \), where the function \( u^\varepsilon(x, y, z, t_0) \) can be constructed according to the following optimization problem for the left and right regions, respectively:

\[
(3.16) \quad u^\varepsilon = \arg \min_{w \in C^1(\mathbb{R}^3 \times \bar{\Omega})} \frac{1}{p + 1} \frac{1}{q + 1} v(-) + \frac{1}{p} \sum_{i=0}^{p} \sum_{j=0}^{q} \sum_{k=0}^{v} \left( w(x_i, y_j, z_k, t_0) - u^\delta_{i,j,k}(t_0) \right)^2
\]

\[+
\varepsilon(-)(t_0) \left( \left\| \frac{\partial^2 w}{\partial x^2} \right\|_{L^2(\mathbb{R}^3 \times \bar{\Omega})}^2 + \left\| \frac{\partial^2 w}{\partial y^2} \right\|_{L^2(\mathbb{R}^3 \times \bar{\Omega})}^2 + \left\| \frac{\partial^2 w}{\partial z^2} \right\|_{L^2(\mathbb{R}^3 \times \bar{\Omega})}^2 \right),
\]

\[
(3.17) \quad u^\varepsilon = \arg \min_{w \in C^1(\mathbb{R}^3 \times \Omega)} \frac{1}{p + 1} \frac{1}{q + 1} v(+) + \frac{1}{p} \sum_{i=0}^{p} \sum_{j=0}^{q} \sum_{k=0}^{v} \left( w(x_i, y_j, z_k, t_0) - u^\delta_{i,j,k}(t_0) \right)^2
\]

\[+
\varepsilon(+)(t_0) \left( \left\| \frac{\partial^2 w}{\partial x^2} \right\|_{L^2(\mathbb{R}^3 \times \Omega)}^2 + \left\| \frac{\partial^2 w}{\partial y^2} \right\|_{L^2(\mathbb{R}^3 \times \Omega)}^2 + \left\| \frac{\partial^2 w}{\partial z^2} \right\|_{L^2(\mathbb{R}^3 \times \Omega)}^2 \right),
\]

where the regularization parameters \( \varepsilon(\tau)(t_0) \) satisfy

\[
\frac{1}{p + 1} \frac{1}{q + 1} v(-) + \frac{1}{p} \sum_{i=0}^{p} \sum_{j=0}^{q} \sum_{k=0}^{v} \left( u^\varepsilon(x_i, y_j, z_k, t_0) - u^\delta_{i,j,k}(t_0) \right)^2 = \delta^4,
\]

\[
\frac{1}{p + 1} \frac{1}{q + 1} v(+) + \frac{1}{p} \sum_{i=0}^{p} \sum_{j=0}^{q} \sum_{k=0}^{v} \left( u^\varepsilon(x_i, y_j, z_k, t_0) - u^\delta_{i,j,k}(t_0) \right)^2 = \delta^4.
\]

According to [32, Theorem 2.1] and [33, Theorem 3.3], the following assertion holds.

**Proposition 3.4.** Suppose that, for a.e. \( t \in \bar{T}, u(\cdot, \cdot, t) \in H^2(\mathbb{R}^2 \times \Omega) \). Let \( u^\varepsilon(x, y, z, t) \) be the minimizer of the problems (3.16) and (3.17), with \( t_0 \) replaced with \( t \). Then, for a.e. \( t \in \bar{T} \) and \( \varepsilon = \delta^2 \),

\[
\|u^\varepsilon(\cdot, \cdot, t) - u(\cdot, \cdot, t)\|_{H^1(\mathbb{R}^2 \times \Omega)} \leq C_{2d}^{1/4} + C_3 \sqrt{\delta},
\]

where \( d = \max\{d_1, d_2, d_3\} \), \( C_2 \) and \( C_3 \) are constants which depend on the domain \( \mathbb{R}^2 \times \Omega \) and the quantity \( \|\Delta u(x, y, z, t)\|_{L^2(\mathbb{R}^2 \times \Omega)} \).
Using Propositions 3.3 and 3.4 and the triangle inequality \( \|f^\delta - f^*\|_{L^2(\mathbb{R}^2 \times \Omega)} \leq \|f^\delta - f_0\|_{L^2(\mathbb{R}^2 \times \Omega)} + \|f_0 - f^*\|_{L^2(\mathbb{R}^2 \times \Omega)} \), it is relatively straightforward to prove the following theorem.

**Theorem 3.5.** \( f^\delta \), defined in (3.15), is a stable approximation of the exact source function \( f^* \) for problem (IP). Moreover, it has the convergence rate

\[
\|f^\delta - f^*\|_{L^2(\mathbb{R}^2 \times \Omega)} = \mathcal{O}(\mu \ln \mu + d^{1/4} + \sqrt{\delta}).
\]

In addition, if \( \mu = \mathcal{O}(\delta^{1/2}) \) (\( \epsilon \) is any positive number) and \( d^{1/4} = \mathcal{O}(\sqrt{\delta}) \), the following estimate holds:

\[
\|f^* - f^\delta\|_{L^2(\mathbb{R}^2 \times \Omega)} = \mathcal{O}(\sqrt{\delta}).
\]

Based on the above analysis, we build an efficient regularization algorithm for the three-dimensional nonlinear-source inverse problem (IP), as shown below.

**Algorithm 3.1** Asymptotic expansion-regularization (AER) algorithm for (IP).

1: if The data for the full measurements \( \{u^\delta_{i,j,k}, (u_x)^\delta_{i,j,k}, (u_y)^\delta_{i,j,k}, (u_z)^\delta_{i,j,k}\} \) are given then
2: break;
3: else
4: if The measurements \( \{u^\delta_{i,j,k}\} \) are provided then
5: Construct the smoothed data \( \{u^\epsilon, \alpha u_x^\epsilon, \alpha u_y^\epsilon, \alpha u_z^\epsilon\} \) by solving (3.16) and (3.17);
6: end if
7: end if
8: Calculate the approximate source function \( f^\delta \) using formula (3.15).

---

**4. Derivation and proofs of main results.**

**4.1. Proof of Theorem 3.1.** To prove Theorem 3.1 and estimate its accuracy ((3.6) – (3.11)), we use the asymptotic method of inequalities [34]. According to this method, a solution to (1.1) exists if there exist continuous functions \( \alpha(x, y, z, t, \mu) \) and \( \beta(x, y, z, t, \mu) \), called, respectively, lower and upper solutions of (1.1). First, we recall the definitions of upper and lower solutions and their role in the construction of solution (1.1) [34, 35, 36].

**Definition 4.1.** The functions \( \beta(x, y, z, t, \mu) \) and \( \alpha(x, y, z, t, \mu) \) are called upper and lower solutions of the problem (1.1), if they are continuous, twice continuously differentiable in \( x, y, z \), respectively, and, for sufficiently small \( \mu \), satisfy the following conditions:

\[ \alpha(x, y, z, t, \mu) \leq \beta(x, y, z, t, \mu) \text{ for } (x, y, z, t) \in \mathbb{R}^2 \times \bar{\Omega} \times \bar{T}. \]

\[ L[\alpha] := \mu \Delta \alpha - \frac{\partial \alpha}{\partial t} + \alpha \left( \frac{\partial \alpha}{\partial x} + \frac{\partial \alpha}{\partial y} + \frac{\partial \alpha}{\partial z} \right) - f(x, y, z) \geq 0, \quad (x, y, z, t) \in \mathbb{R}^2 \times \bar{\Omega} \times \bar{T}; \]

\[ L[\beta] := \mu \Delta \beta - \frac{\partial \beta}{\partial t} + \beta \left( \frac{\partial \beta}{\partial x} + \frac{\partial \beta}{\partial y} + \frac{\partial \beta}{\partial z} \right) - f(x, y, z) \leq 0, \quad (x, y, z, t) \in \mathbb{R}^2 \times \bar{\Omega} \times \bar{T}. \]

\[ \alpha(x, y, -a, t, \mu) \leq u^a(x, y) \leq \beta(x, y, -a, t, \mu), \quad \alpha(x, y, a, t, \mu) \leq u^a(x, y) \leq \beta(x, y, a, t, \mu). \]
Lemma 4.2. ([35]) Let there be an upper \(\beta(x, y, z, t, \mu)\) and a lower \(\alpha(x, y, z, t, \mu)\) solutions to problem (1.1) satisfying conditions (C1)–(C3) in Definition 4.1. Then, under Assumptions 2.1–2.4, there exists a solution \(u(x, y, z, t, \mu)\) to problem (1.1) that satisfies the inequalities

\[
\alpha(x, y, z, t, \mu) \leq u(x, y, z, t, \mu) \leq \beta(x, y, z, t, \mu), \quad (x, y, z, t) \in \mathbb{R}^2 \times \bar{\Omega} \times \bar{T}.
\]

Moreover, the functions \(\beta(x, y, z, t, \mu)\) and \(\alpha(x, y, z, t, \mu)\) satisfy the following estimates:

\[
\begin{align*}
\beta(x, y, z, t, \mu) - \alpha(x, y, z, t, \mu) &= O(\mu^n), \\
u(x, y, z, t, \mu) &= \alpha(x, y, z, t, \mu) + O(\mu^n) = U_{n-1}(x, y, z, t, \mu) + O(\mu^n).
\end{align*}
\]

Lemma 4.3. ([34, 36]) Lemma 4.2 also remains valid in the case in which the functions \(\alpha(x, y, z, t, \mu)\) and \(\beta(x, y, z, t, \mu)\) are continuous and their derivatives with respect to \(x, y, z\) have discontinuities from the class \(C^2\) in the direction of the normal to surfaces on which these solutions are not smooth, and the limit values of the derivatives on the surface \(h(x, y, t)\) satisfy the following condition:

(C4): \(\frac{\partial \alpha}{\partial n}(x, y, h_{\alpha}(x, y, t) - 0, t, \mu) - \frac{\partial \alpha}{\partial n}(x, y, h_{\alpha}(x, y, t) + 0, t, \mu) \geq 0,\)

where \(h_{\alpha}(x, y, t)\) is the surface on which the lower solution is not smooth;

(C4): \(\frac{\partial \beta}{\partial n}(x, y, h_{\beta}(x, y, t) - 0, t, \mu) - \frac{\partial \beta}{\partial n}(x, y, h_{\beta}(x, y, t) + 0, t, \mu) \geq 0,\)

where \(h_{\beta}(x, y, t)\) is the surface on which the upper solution is not smooth.

The proofs of Lemmas 4.2–4.3 can be found in [34, 35]. Thus, to prove Theorem 3.1, it is necessary to construct the lower and upper solutions \(\alpha(x, y, z, t, \mu)\) and \(\beta(x, y, z, t, \mu)\). Under conditions (C1)–(C4) for \(\alpha(x, y, z, t, \mu)\) and \(\beta(x, y, z, t, \mu)\), estimates (3.2) and (3.3) will follow directly from Lemma 4.2.

We now begin the proof of Theorem 3.1.

Proof. Following the main idea in [37], we construct the upper and lower solutions \(\beta(-), \beta(+), \alpha(-), \alpha(+)\) and curves \(h_{\beta}, h_{\alpha}\) as a modification of asymptotic representation (3.1).

We introduce a positive function \(\rho(x, y, t)\), which will be defined later in (4.21), and use the notations \(\rho_{\beta}(x, y, t) = -\rho(x, y, t)\) and \(\rho_{\alpha}(x, y, t) = \rho(x, y, t)\) to aid in defining the surfaces \(h_{\beta}(x, y, t)\) and \(h_{\alpha}(x, y, t)\), which in turn will determine the position of the inner transition layer for the upper and lower solution, in the form

\[
\begin{align*}
h_{\beta}(x, y, t) &= \sum_{i=0}^{n+1} \mu^i h_i(x, y, t) + \mu^{n+1} \rho_{\beta}(x, y, t), \\
h_{\alpha}(x, y, t) &= \sum_{i=0}^{n+1} \mu^i h_i(x, y, t) + \mu^{n+1} \rho_{\alpha}(x, y, t).
\end{align*}
\]

In the vicinity of the surface \(h_{\beta}(x, y, t)\), we pass to the local coordinates \((r_{\beta}, l, m)\) according to the following equations:
where \( r_\beta \) is the distance from the surface \( h_\beta(x, y, t) \) along the normal to it, \( l \) and \( m \) are the coordinates of the point on the \( x \) and \( y \) axes respectively from which this normal is drawn, and the derivatives of the function \( h_\beta \) at each time \( t \) are taken at \( x = l \) and \( y = m \).

Similarly, in the vicinity of the surface \( h_\alpha(x, y, t) \) we pass to the local coordinates

\[
x = l - \frac{r_\alpha(h_\alpha)_x}{\sqrt{1 + (h_\alpha)_x^2 + (h_\alpha)_y^2}}, \quad y = m - \frac{r_\alpha(h_\alpha)_y}{\sqrt{1 + (h_\alpha)_x^2 + (h_\alpha)_y^2}},
\]
\[
z = h_\alpha + \frac{r_\alpha}{\sqrt{1 + (h_\alpha)_x^2 + (h_\alpha)_y^2}} = \hat{h}_{n+1}(l, m, t) + \frac{r_\alpha}{\sqrt{1 + (h_\alpha)_x^2 + (h_\alpha)_y^2}} + \mu^{n+1} \rho_\alpha(l, m, t),
\]

where \( r_\alpha \) is the distance from the surface \( h_\alpha(x, y, t) \) along the normal to it.

In the neighborhood of the surfaces \( h_\beta(x, y, t) \) and \( h_\alpha(x, y, t) \), we introduce the extended variables

\[
(4.4) \quad \xi_\beta = \frac{r_\beta}{\mu}, \quad \xi_\alpha = \frac{r_\alpha}{\mu}.
\]

The upper and lower solutions of problem (1.1) will be constructed separately in the domains \( \bar{D}^{(-)}_\beta, \bar{D}^{(+)\alpha} \) and \( \bar{D}^{(-)}_\alpha, \bar{D}^{(+)\beta} \), in which the surfaces \( h_\beta(x, y, t) \) and \( h_\alpha(x, y, t) \) divide the domain \( \mathbb{R}^2 \times \bar{\Omega} \times \bar{T} \) at each moment of time \( t \):

\[
(4.5) \quad \beta = \begin{cases} 
\beta^{(-)}(x, y, z, t, \mu), & (x, y, z, t) \in \bar{D}^{(-)}_\beta := \{(x, y, z, t) \in \mathbb{R}^2 \times [-a, h_\beta] \times \bar{T}\}, \\
\beta^{(+)}(x, y, z, t, \mu), & (x, y, z, t) \in \bar{D}^{(+)\beta} := \{(x, y, z, t) \in \mathbb{R}^2 \times [h_\beta, a] \times \bar{T}\},
\end{cases}
\]
\[
(4.6) \quad \alpha = \begin{cases} 
\alpha^{(-)}(x, y, z, t, \mu), & (x, y, z, t) \in \bar{D}^{(-)}_\alpha := \{(x, y, z, t) \in \mathbb{R}^2 \times [-a, h_\alpha] \times \bar{T}\}, \\
\alpha^{(+)}(x, y, z, t, \mu), & (x, y, z, t) \in \bar{D}^{(+)\alpha} := \{(x, y, z, t) \in \mathbb{R}^2 \times [h_\alpha, a] \times \bar{T}\}.
\end{cases}
\]

We match the functions \( \beta^{(-)}(x, y, z, t, \mu), \beta^{(+)}(x, y, z, t, \mu) \) and \( \alpha^{(-)}(x, y, z, t, \mu), \alpha^{(+)}(x, y, z, t, \mu) \) on the surfaces \( h_\beta(x, y, t) \) and \( h_\alpha(x, y, t) \), respectively, so that \( \beta(x, y, t, \mu) \) and \( \alpha(x, y, t, \mu) \) are continuous on these surfaces and the following equations hold:

\[
(4.7) \quad \begin{cases} 
\beta^{(-)}(x, y, h_\beta, t, \mu) = \beta^{(+)}(x, y, h_\beta, t, \mu) = \frac{\tilde{u}^{(-)}(x, y, h_\beta) + \tilde{u}^{(+)}(x, y, h_\beta)}{2}, \\
\alpha^{(-)}(x, y, h_\alpha, t, \mu) = \alpha^{(+)}(x, y, h_\alpha, t, \mu) = \frac{\tilde{u}^{(-)}(x, y, h_\alpha) + \tilde{u}^{(+)}(x, y, h_\alpha)}{2}.
\end{cases}
\]
Note that we do not match the derivatives of the upper and lower solutions on the surfaces \( h_{\beta}(x, y, t) \) and \( h_{\alpha}(x, y, t) \), respectively, so the derivatives \( \partial \beta / \partial z \) and \( \partial \alpha / \partial z \) have discontinuity points, and therefore fulfillment of condition (C4) is required to hold.

We construct the functions \( \beta^{(\mp)} \) and \( \alpha^{(\mp)} \) in the following forms:

\[
\begin{align*}
\beta^{(\pm)} &= \eta_{n+1}^{(\pm)}|_{\xi_{1},\xi_{2}} + \mu^{n+1} \left( \epsilon^{(\pm)}(x, y, z) + q_{0}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t) + \mu q_{1}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t) \right), \\
\alpha^{(\pm)} &= \eta_{n+1}^{(\pm)}|_{\xi_{1},\xi_{2}} - \mu^{n+1} \left( \epsilon^{(\pm)}(x, y, z) + q_{0}^{(\pm)}(\xi_{\alpha}, l, m, h_{\alpha}, t) + \mu q_{1}^{(\pm)}(\xi_{\alpha}, l, m, h_{\alpha}, t) \right),
\end{align*}
\]

where the functions \( \epsilon^{(\pm)}(x, y, z) \) should be designed in such a way that condition (C2) is satisfied for \( \beta^{(\pm)} \) and \( \alpha^{(\pm)} \) in (4.8). The functions \( q_{0}^{(\pm)} \) eliminate residuals of order \( \mu^{n} \) arising in \( L[\beta] \) and \( L[\alpha] \) and the residuals of order \( \mu^{n+1} \) under the condition of continuous matching of the upper solution (4.7), which arise as a result of modifying the outer part by adding \( \epsilon^{(\pm)}(x, y, z) \). The functions \( q_{1}^{(\pm)} \) eliminate residuals of order \( \mu^{n+1} \) arising in \( L[\beta] \) and \( L[\alpha] \) by adding \( \epsilon^{(\pm)}(x, y, z) \) and \( q_{0}^{(\pm)} \).

We now define the functions \( \epsilon^{(\pm)}(x, y, z) \) from the following equations:

\[
\begin{align*}
\varphi^{(\pm)} \left( \frac{\partial \epsilon^{(\pm)}}{\partial x} + \frac{\partial \epsilon^{(\pm)}}{\partial y} + \frac{\partial \epsilon^{(\pm)}}{\partial z} \right) + \epsilon^{(\pm)} \left( \frac{\partial \varphi^{(\pm)}}{\partial x} + \frac{\partial \varphi^{(\pm)}}{\partial y} + \frac{\partial \varphi^{(\pm)}}{\partial z} \right) &= -R,
\end{align*}
\]

where \( R, R^{(-)}, R^{(+)}, \) are some positive constants, independent of \( x, y, z \). The functions \( \epsilon^{(\pm)}(x, y, z) \) have explicit solution of the type (2.25) where \( W^{(\pm)} = \frac{-R}{\varphi^{(\pm)}} \) and since \( \varphi^{(\pm)}(x, y, z) < 0 \) and \( \varphi^{(\pm)}(x, y, z) > 0 \), \( \epsilon^{(\pm)}(x, y, z) > 0 \) for \( (x, y, z) \in \mathbb{R}^{3} \times \Omega \).

We define the functions \( q_{0}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t) \) as solutions of the equations

\[
\begin{align*}
\frac{\partial^{2} q_{0}^{(\pm)}}{\partial \xi_{\beta}^{2}} + \frac{\partial \epsilon^{(\pm)}}{\partial \xi_{\beta}} \left( q_{0}^{(\pm)} \left( h_{01}\left( h_{01}^{2} + h_{02}^{2} + 1 \right) + \bar{u}(1 - h_{01} - h_{02}) \right) \right) &= b_{1}^{(\pm)}(\xi_{\beta}, l, m, t) \frac{\partial \rho_{\beta}}{\partial t} \\
+ b_{2}^{(\pm)}(\xi_{\beta}, l, m, t) \frac{\partial \rho_{\beta}}{\partial m} + b_{3}^{(\pm)}(\xi_{\beta}, l, m, t) \rho_{\beta} + b_{4}^{(\pm)}(\xi_{\beta}, l, m, t) \frac{\partial \rho_{\beta}}{\partial t} + b_{5}^{(\pm)}(\xi_{\beta}, l, m, t) \\
&:= H_{q_{0}^{(\pm)}}^{(\pm)}(\xi_{\beta}, l, m, t),
\end{align*}
\]

where \( b_{1}^{(\pm)}(\xi_{\beta}, l, m, t) - b_{5}^{(\pm)}(\xi_{\beta}, l, m, t) \) are known functions, and, particularly, \( b_{4}^{(\pm)}(\xi_{\beta}, l, m, t) = \frac{\partial Q_{0}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t)}{\partial \xi_{\beta}} \sqrt{1 + h_{01}^{2} + h_{02}^{2}} \).

The boundary conditions for \( q_{0}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t) \) follow from equation (4.7), by matching the upper solution and taking into account conditions at \( \xi_{\beta} = 0 \) for the functions \( Q_{0}^{(\pm)}(\xi_{\beta}, l, m, h_{\beta}, t) \).
Using (4.10) and (4.11), we write the functions \( q_0^{(\mp)}(\xi, l, m, h, t) \) in the explicit form:

\[
q_0^{(\mp)}(\xi, l, m, h, t) = J^{(\mp)}(\xi, h_0) \left( p^{(\mp)}_0(l, m, h_0) + \int_0^{\xi_s} \frac{1}{J^{(\mp)}(s, h_0)} \int_{\mp\infty}^{s} H_q^{(\mp)}(\eta, l, m, t) d\eta ds \right).
\]

We define the functions \( q_1^{(\mp)}(\xi, l, m, h, t) \) from the following equation:

\[
\frac{\partial^2 q_1^{(\mp)}}{\partial \xi_3^{2\mp}} + \frac{\partial}{\partial \xi_\beta} \left( q_1^{(\mp)} h_{0\ell}(h_0^2 h_{0m}^2 + 1) + \tilde{u}(1 - h_0 - h_{0m}) \right) = H_{q1}^{(\mp)}(\xi, l, m, t),
\]

where \( H_{q1}^{(\mp)}(\xi, l, m, t) \) depend on known functions \( h_{0,1}, u_{0,1}, Q_{0,1}, \rho_\beta, \epsilon^{(\mp)}, \) and \( q_0^{(\mp)} \). For equation (4.13), we infer that the boundary condition is

\[
q_1^{(\mp)}(0, l, m, h, t) = 0, \quad q_1^{(\mp)}(\xi, l, m, h, t) \to 0 \text{ for } \xi \to \mp\infty.
\]

Replacing \( \rho_\beta \) with \( \rho_\alpha \) and \( \xi_\beta \) with \( \xi_\alpha \) in (4.10)–(4.13), we define the functions \( q_0^{(\mp)}(\xi, l, m, h, t) \) and \( q_1^{(\mp)}(\xi, l, m, h, t) \) that appear in the functions \( \alpha^{(\mp)} \).

The functions \( q_0^{(\mp)} \) and \( q_1^{(\mp)} \) satisfy exponential estimates of the types in (2.35) and (2.36).

Now, we have to show that the functions \( \beta(x, y, z, t, \mu) \) and \( \alpha(x, y, z, t, \mu) \) are upper and lower solutions to problem (1.1). To do this, we check conditions (C1)–(C4).

First, we check that condition (C1) has been fulfilled, with regard to the ordering of the lower and upper solutions. To do this, we consider three regions that illustrate the difference between the upper and lower solutions, \( \beta - \alpha \):

\[
\beta - \alpha = \begin{cases} 
\beta^{(-)} - \alpha^{(-)}, & I = \{(x, y, z, t) : \mathbb{R}^2 \times (-a, h_\beta(x, y, t)) \times \bar{T} \}, \\
\beta^{(+)} - \alpha^{(+)}, & II = \{(x, y, z, t) : \mathbb{R}^2 \times [h_\beta(x, y, t), h_\alpha(x, y, t)) \times \bar{T} \}, \\
\beta^{(+)} - \alpha^{(+)} & III = \{(x, y, z, t) : \mathbb{R}^2 \times [h_\alpha(x, y, t), a] \times \bar{T} \}.
\end{cases}
\]

First, we find the variables on which \( \beta \) and \( \alpha \) depend.

\[
z = \hat{h}_{n+1}(l, m, t) + \frac{r_\beta}{\sqrt{1 + (\hat{h}_{n+1})^2_x + (\hat{h}_{n+1})^2_y}} - \mu^{n+1} \rho(l, m, t) + \mathcal{O}(\mu^{n+1})
\]

\[
= \hat{h}_{n+1}(l, m, t) + \frac{r_\alpha}{\sqrt{1 + (\hat{h}_{n+1})^2_x + (\hat{h}_{n+1})^2_y}} + \mu^{n+1} \rho(l, m, t) + \mathcal{O}(\mu^{n+1}).
\]

We rewrite (2.17) in the following form:
The difference between the upper and lower solutions in region II:

\[ \xi_{\beta} = \frac{z - h_\beta}{\mu} \sqrt{1 + (h_\beta)^2_x + (h_\beta)^2_y}, \quad \xi_{\alpha} = \frac{z - h_\alpha}{\mu} \sqrt{1 + (h_\alpha)^2_x + (h_\alpha)^2_y}, \]

from where we find:

\[ \Delta \xi = \xi_{\beta} - \xi_{\alpha} = 2\mu^n \left( \rho \sqrt{1 + (h_0)^2_x + (h_0)^2_y} + \frac{(\rho x(h_0)_x + \rho y(h_0)_y)(h_0 - y)}{\sqrt{1 + (h_0)^2_x + (h_0)^2_y}} \right) + O(\mu^{n+1}). \]

For region II, the following holds:

\[ 0 \leq \xi_{\beta} \leq 2\mu^n \rho(l, m, t) \sqrt{1 + (h_0)^2_x + (h_0)^2_y} + O(\mu^{n+1}), \]

\[ 0 \geq \xi_{\alpha} \geq -2\mu^n \rho(l, m, t) \sqrt{1 + (h_0)^2_x + (h_0)^2_y} + O(\mu^{n+1}), \]

\[ \xi_{\beta} - \xi_{\alpha} = 2\mu^n \rho(l, m, t) \sqrt{1 + (h_0)^2_x + (h_0)^2_y} + O(\mu^{n+1}). \]

We can write an expression for the difference between the upper and lower solutions:

\[ \beta^{(+)} - \alpha^{(-)} = \sum_{i=0}^{n} \mu^i \left( Q_+^{(i)}(\xi_{\beta}, l, m, h_\beta, t) - Q_-^{(i)}(\xi_{\alpha}, l, m, h_\alpha, t) \right) \text{ and } O(\mu^{n+1}). \]

Expanding equation (4.15) in series, and taking into account the notation (2.29), equation (2.32) and the fact that in region II \( \xi_{\beta} = O(\mu^n) \) and \( \xi_{\alpha} = O(\mu^n) \), we obtain an expression for the difference between the upper and lower solutions in region II:

\[ \beta^{(+)} - \alpha^{(-)} = \frac{\partial Q_+^{(0)}(0, x, y, h_0(x, y, t), t)}{\partial \xi} (0, x, y, h_0(x, y, t), t) \xi_{\beta} - \frac{\partial Q_-^{(0)}(0, x, y, h_0(x, y, t), t)}{\partial \xi} (0, x, y, h_0(x, y, t), t) \xi_{\alpha} + O(\mu^{n+1}) \]

\[ = 2\mu^n \rho(l, m, t) \sqrt{1 + (h_0)^2_x + (h_0)^2_y} \cdot \Phi^{(+)}(0, h_0(x, y, t)) + O(\mu^{n+1}). \]

Using equation (2.34) and Assumption 2.3, we can verify that \( \Phi^{(+)}(0, h_0(x, y, t)) > 0 \), and, for positive values of \( \rho \) and for a sufficiently small \( \mu \), we obtain \( \beta - \alpha > 0 \), \( (x, y, z, t) \in \Omega II \).

We now consider the difference between the upper and lower solutions at region III, where \( \xi_{\alpha} \geq 0, \xi_{\beta} = \xi_{\alpha} + \Delta \xi \). Using exponential properties of the functions \( Q_i^{(+)} \) and \( q_0^{(+)} \), we obtain:

\[ \beta - \alpha = \beta^{(+)} - \alpha^{(+)} = \sum_{i=0}^{n} \mu^i \left( Q_i^{(+)}(\xi_{\beta}, l, m, h_\beta, t) - Q_i^{(+)}(\xi_{\alpha}, l, m, h_\alpha, t) \right) \]

\[ + 2\mu^{n+1} \epsilon^{(+)} + \mu^{n+1} \left( q_0^{(+)}(\xi_{\beta}, l, m, h_\beta, t) - q_0^{(+)}(\xi_{\alpha}, l, m, h_\alpha, t) \right) + O(\mu^{n+2}) \]

\[ = 2\mu^{n+1} \epsilon^{(+)} + \frac{\partial Q_0^{(+)}(\xi_{\alpha}, l, m, h_\alpha, t)}{\partial \xi} (\xi_{\beta} - \xi_{\alpha}) + O(\mu^{n+1}) \exp(-\kappa_1 \xi_{\alpha}) + O(\mu^{n+2}). \]
where $\kappa_1 > 0$ is a constant independent of $\xi_\alpha, l, m, t$.

Taking into account estimates (2.35) and (2.36) and the equality $\xi_\beta - \xi_\alpha = O(\mu^n)$, we obtain an expression for the difference between the upper and lower solutions in region III:

$$
\beta - \alpha \leq 2\mu^{n+1}\epsilon^{(+)} + \{C_4\mu^n \exp(-\kappa_0 \xi_\alpha) - C_5\mu^{n+1} \exp(-\kappa_1 \xi_\alpha)\} + O(\mu^{n+2}),
$$

(4.18)

where $\kappa_0 > 0$, $C_4 > 0$ and $C_5 > 0$ are some constants independent of $\xi_\alpha, l, m, t$.

Let $\kappa_0 \leq \kappa_1$, the expression in the brackets in (4.18) is positive, since $C_4 > C_5\mu$ for a sufficiently small $\mu$. Hence, $\beta - \alpha > 0$.

Let $\kappa_0 > \kappa_1$. Consider the region $x \in \mathbb{R}, y \in \mathbb{R}, z \in [h_\alpha, h_\alpha + \frac{N\mu}{\sqrt{1+(h_\alpha)^2}}, t] \in \mathcal{T}$, where $N > 0$. In this region, the value $r_\alpha$ changes on the interval $[0, N\mu]$ and the inequality $\exp(-\kappa_0 \xi_\alpha) \geq \exp(-\kappa_0 N)$ is satisfied, and so the bracketed expression in (4.18) is positive if $\mu$ is small enough due to the component $C_4\mu^n \exp(-\kappa_0 \xi_\alpha)$. Hence, $\beta - \alpha > 0$.

Now we choose a number $N$ large enough to satisfy the inequality $C_5 \exp(-\kappa_1 N) < 2\epsilon^{(+)}$.

When $z \in [h_\alpha + \frac{N\mu}{\sqrt{1+(h_\alpha)^2}}, a]$, due to the choice of the number $N$ we obtain

$$2\mu^{n+1}\epsilon^{(+)} - C_5\mu^{n+1} \exp(-\kappa_1 \xi_\alpha) \geq \mu^{n+1}(2\epsilon^{(+)} - C_5 \exp(-\kappa_1 N)) > 0.
$$

Thus, $\beta(x, y, z, t, \mu) - \alpha(x, y, z, t, \mu) > 0$ everywhere in region III. The proof of the inequality $\beta(x, y, z, t, \mu) - \alpha(x, y, z, t, \mu) > 0$ for region I is developed in the same way as for region III.

The method of constructing the upper and lower solutions implies the inequalities

$$L[\beta] = -\mu^{n+1}R + O(\mu^{n+2}) < 0, \quad L[\alpha] = \mu^{n+1}R + O(\mu^{n+2}) > 0,$$

where $R$ is a constant from (4.9). This verifies condition (C2).

Condition (C3) is satisfied for sufficiently large values $R^{(-)}$ and $R^{(+)}$ in the boundary conditions of equation (4.9).

We now check condition (C4) for the upper solution, and expand it in powers of $\mu$; due to the matching of the asymptotics (2.32) and (2.45), the coefficients at $\mu^i$ for $i = 1, \ldots, n$ are equal to zero, and the coefficient at $\mu^{n+1}$ includes only terms that arise as a result of the modification of the asymptotic expansion:

$$
\mu \left( \frac{\partial \beta^{(-)}}{\partial n} - \frac{\partial \beta^{(+)}}{\partial n} \right)_{h_\beta} = \mu^{n+1} \left( \frac{\partial q_0^{(-)}}{\partial \xi_\beta} (0, x, y, h_\beta, t) - \frac{\partial q_0^{(+)}}{\partial \xi_\beta} (0, x, y, h_\beta, t) \right) + O(\mu^{n+2}).
$$

(4.19)

Using the explicit solution for $q_0^{(+)}(0, x, y, h_\beta, t)$ (4.12), we find

$$
\frac{\partial q_0^{(-)}}{\partial \xi_\beta} (0, x, y, h_\beta, t) - \frac{\partial q_0^{(+)}}{\partial \xi_\beta} (0, x, y, h_\beta, t) = \frac{\partial \rho_\beta(x, y, t)}{\partial t} \left( \int_{-\infty}^{0} b_4^{(-)} (s, x, y, t) ds + \int_0^{+\infty} b_4^{(+)} (s, x, y, t) ds \right) + \frac{\partial \rho_\beta(x, y, t)}{\partial t} H_1(x, y, t)
$$

$$
+ \frac{\partial \rho_\beta(x, y, t)}{\partial t} H_2(x, y, t) + \rho_\beta(x, y, t) H_3(x, y, t) + H_4(x, y, t),
$$

(4.20)
where

\[ H_1(x,y,t) = \int_{-\infty}^{0} b_1^-(s,x,y,t) \, ds + \int_{0}^{+\infty} b_1^+(s,x,y,t) \, ds, \]

\[ H_2(x,y,t) = \int_{-\infty}^{0} b_2^-(s,x,y,t) \, ds + \int_{0}^{+\infty} b_2^+(s,x,y,t) \, ds, \]

\[ H_3(x,y,t) = \int_{-\infty}^{0} b_3^-(s,x,y,t) \, ds + \int_{0}^{+\infty} b_3^+(s,x,y,t) \, ds, \]

\[ H_4(x,y,t) = \left( \epsilon^+ - \epsilon^- \right) \left( \frac{-h_0t(h_0^2 + h_0^2 + 1) + \phi_0(h_0^2 + h_0^2 - 1)}{\sqrt{1 + h_0^2 + h_0^2}} \right) + \int_{-\infty}^{0} b_5^-(s,x,y,t) \, ds + \int_{0}^{+\infty} b_5^+(s,x,y,t) \, ds. \]

We choose the function \( \rho_\beta(x,y,t) \) as a solution to the problem

\[
\begin{cases}
\frac{\partial \rho_\beta}{\partial t} \left( \varphi^+ - \varphi^- \right) \sqrt{1 + h_0^2 + h_0^2} \\
\quad - H_1(x,y,t) \frac{\partial \rho_\beta}{\partial x} - H_2(x,y,t) \frac{\partial \rho_\beta}{\partial y} - H_3(x,y,t) \rho_\beta - H_4(x,y,t) + \sigma,
\end{cases}
\]

\[ \rho_\beta(x,y,0) = \rho^0(x,y), \quad \rho_\beta(x,y,t) = \rho_\beta(x + M,t) = \rho_\beta(x + L,t), \quad t \in \bar{T}. \]

Since the difference \( \varphi^+ - \varphi^- \) is positive, and we choose the constant \( \sigma \) and the function \( \rho^0(x,y) \) to be positive for any \( x,y \), then the solution \( \rho(x,y,t) \) of the equation (4.21) is also positive for a sufficiently large \( \sigma \).

For such \( \rho(x,y,t) \), we obtain:

\[ \mu \left( \frac{\partial \beta^-}{\partial n} - \frac{\partial \beta^+}{\partial n} \right) \bigg|_{h(l,m,t)=h_3(l,m,t)} = \mu^{n+1} \sigma + O(\mu^{n+2}) > 0. \]

Similarly, condition (C4) is satisfied for the functions \( \alpha^{(+)} \), and the constructed upper and lower solutions guarantee the existence of a solution \( u(x,y,z,t,\mu) \) to the problem (1.1) satisfying the inequalities

\[ \alpha(x,y,z,t,\mu) \leq u(x,y,z,t,\mu) \leq \beta(x,y,z,t,\mu), \]

by addition, estimates (3.2) and (3.3) are valid.

It is possible to show that the estimate (3.4) is also holds using technique represented in [36] by estimating the difference \( Z_n(x,y,t,\mu) \equiv u(x,y,t,\mu) - U_n(x,y,t,\mu) \); the function \( Z_n(x,y,t,\mu) \) satisfies the equation

\[ \Delta Z_n - \frac{1}{\mu} \frac{\partial Z_n}{\partial t} - KZ_n = -KZ_n + \frac{1}{\mu} \left( \frac{\partial}{\partial x} + \frac{\partial}{\partial y} + \frac{\partial}{\partial z} \right) \int_{u}^{U_n} (s) \, ds + \mu^n \psi(x,y,t,\mu), \]

(4.24)
for \((x, y, t) \in \mathbb{R} \times \bar{\Omega} \times \bar{T}\), with zero boundary conditions, where \(|\psi(x, y, t, \mu)| \leq c_0\) and \(c_0\) is a constant independent of \(x, y, z, t, \mu\). Using the estimates from Lemma 4.2, and solving (4.24) with a Green’s function for the parabolic operator [38], taking into account the estimates [38, Page 49] we obtain \(\frac{\partial Z_n}{\partial x} = \mathcal{O}(\mu^n)\), \(\frac{\partial Z_n}{\partial y} = \mathcal{O}(\mu^n)\), \(\frac{\partial Z_n}{\partial z} = \mathcal{O}(\mu^n)\) for \((x, y, t) \in \mathbb{R} \times \bar{\Omega} \times \bar{T}\) and the estimate \(\frac{\partial Z_n}{\partial n} = \mathcal{O}(\mu^n)\) follows directly from (2.30). This completes the proof of Theorem 3.1. 

4.2. Proof of Proposition 1.

Proof. First, we note that the exact source function \(f^*\) has the following representation according to equations (2.21) and (2.22):

\[
\begin{align*}
\phi^* = \begin{cases}
\tilde{u}_0^-(\frac{\partial \tilde{u}_0^-}{\partial x} + \frac{\partial \tilde{u}_0^-}{\partial y} + \frac{\partial \tilde{u}_0^-}{\partial z}), & (x, y, z) \in \mathbb{R}^2 \times (-a, h_0(x, y, t) - \Delta h/2), \\
\tilde{u}_0^+(\frac{\partial \tilde{u}_0^+}{\partial x} + \frac{\partial \tilde{u}_0^+}{\partial y} + \frac{\partial \tilde{u}_0^-}{\partial z}), & (x, y, z) \in \mathbb{R}^2 \times (h_0(x, y, t) + \Delta h/2, a).
\end{cases}
\end{align*}
\]

Let \(\Omega' = (-a, h_0(x, y, t) - \Delta h/2)\). By using Corollary 3.2, we deduce, together with \(|\Omega'| \leq |\Omega| = a\), that

\[
\begin{align*}
\|\varphi^-(x, y, z) - u(x, y, z, t)\|_{L^p(\mathbb{R}^2 \times \Omega')} & \leq C\mu, \\
\left\|\frac{\partial \varphi^-}{\partial x} - \frac{\partial u}{\partial x}\right\|_{L^p(\mathbb{R}^2 \times \Omega')} & \leq C\mu, \\
\left\|\frac{\partial \varphi^-}{\partial y} - \frac{\partial u}{\partial y}\right\|_{L^p(\mathbb{R}^2 \times \Omega')} & \leq C\mu, \\
\left\|\frac{\partial \varphi^-}{\partial z} - \frac{\partial u}{\partial z}\right\|_{L^p(\mathbb{R}^2 \times \Omega')} & \leq C\mu,
\end{align*}
\]
From estimates (4.26), we conclude that
\begin{equation}
\|f^* - f_0\|_{L^p(\mathbb{R}^2 \times \Omega')} \leq \left\| \varphi^*(-) \left( \frac{\partial \varphi(-)}{\partial x} + \frac{\partial \varphi(-)}{\partial y} + \frac{\partial \varphi(-)}{\partial z} \right) - u \left( \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \right) \right\|_{L^p(\mathbb{R}^2 \times \Omega')}
\end{equation}

(4.27)
\begin{equation}
\|f^* - f_0\|_{L^p(\mathbb{R}^2 \times \Omega')} \leq \left\| \varphi^*(-) \left( \frac{\partial \varphi(-)}{\partial x} + \frac{\partial \varphi(-)}{\partial y} + \frac{\partial \varphi(-)}{\partial z} \right) - u \left( \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \right) \right\|_{L^p(\mathbb{R}^2 \times \Omega')}
\end{equation}

\begin{equation}
\leq \left\| \varphi(-) - u \right\|_{L^p(\mathbb{R}^2 \times \Omega')} \left\| \frac{\partial \varphi(-)}{\partial x} + \frac{\partial \varphi(-)}{\partial y} + \frac{\partial \varphi(-)}{\partial z} \right\|_{L^p(\mathbb{R}^2 \times \Omega')}
\end{equation}

\begin{equation}
\leq \left\| \varphi(-) - u \right\|_{L^p(\mathbb{R}^2 \times \Omega')} \left\| \frac{\partial \varphi(-)}{\partial x} + \frac{\partial \varphi(-)}{\partial y} + \frac{\partial \varphi(-)}{\partial z} \right\|_{L^p(\mathbb{R}^2 \times \Omega')}
\end{equation}

\begin{equation}
\leq \left\| \varphi(-) - u \right\|_{L^p(\mathbb{R}^2 \times \Omega')} \left\| \frac{\partial \varphi(-)}{\partial x} + \frac{\partial \varphi(-)}{\partial y} + \frac{\partial \varphi(-)}{\partial z} \right\|_{L^p(\mathbb{R}^2 \times \Omega')}
\end{equation}

\begin{equation}
\leq 3C \left( C \mu + \left\| u \right\|_{W^{1,1}(\mathbb{R}^2 \times \Omega')} \right) \mu =: c_1 \mu.
\end{equation}

Following exactly the same reasoning process, we also derive the following inequality:
\begin{equation}
\|f^* - f_0\|_{L^p(\mathbb{R}^2 \times [h_0 + \Delta h/2, a])} \leq c_2 \mu
\end{equation}

with a constant $c_2$. Now, we note that
\begin{equation}
\|f^* - f_0\|_{L^p(\mathbb{R} \times [h_0 - \Delta h/2, h_0 + \Delta h/2])} \leq \|f^*\|_{L^p(\mathbb{R}^2 \times [h_0 - \Delta h/2, h_0 + \Delta h/2])} + \|f_0\|_{L^p(\mathbb{R}^2 \times [h_0 - \Delta h/2, h_0 + \Delta h/2])} \leq c_3 \mu |\ln \mu|
\end{equation}

with $c_3 = \|f^*\|_{C(\mathbb{R}^2 \times \Omega)} + \|f_0\|_{C(\mathbb{R}^2 \times \Omega)}$. By combining (4.27)–(4.29), we deduce that
\begin{equation}
\|f^* - f_0\|_{L^p(\mathbb{R}^2 \times [-a, a])} \leq \left\| f^* - f_0 \right\|_{L^p(\mathbb{R}^2 \times [-a, h_0 - \Delta h])} + \left\| f^* - f_0 \right\|_{L^p(\mathbb{R}^2 \times [h_0 + \Delta h, a])}
\end{equation}

\begin{equation}
+ \left\| f^* - f_0 \right\|_{L^p(\mathbb{R}^2 \times [h_0 - \Delta h, a])} \leq c_4 \mu^p + c_5 \mu^p + c_6 \mu^p \ln \mu^p,
\end{equation}

which yields the required estimate (3.14), with $C_1 = (c_1^p + c_2^p + c_3^p)^{1/p}$.

\subsection*{4.3. Proof of Theorem 3.5.}

\textbf{Proof.} Let $f_0$ be the pre-approximate source function defined in (3.13). Similarly to the
proof of Proposition 3.3, for small enough $\delta$ we obtain the following inequalities:

\[
\|f^\delta - f_0\|_{L^2(\mathbb{R}^2 \times \Omega')} = \left\| u^\delta \left( \frac{\partial u^\delta}{\partial x} + \frac{\partial u^\delta}{\partial y} + \frac{\partial u^\delta}{\partial z} \right) - u \left( \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \right) \right\|_{L^2(\mathbb{R}^2 \times \Omega')}
\leq \left\| u^\delta - u \right\|_{L^2(\mathbb{R}^2 \times \Omega')} \left( \|u^\delta - u\|_{H^1(\mathbb{R}^2 \times \Omega')} + \|u\|_{H^1(\mathbb{R}^2 \times \Omega')} \right) + \left\| u \right\|_{L^2(\mathbb{R}^2 \times \Omega')} \left\| u^\delta - u \right\|_{H^1(\mathbb{R}^2 \times \Omega')}
\leq 2 \left( \|u\|_{H^1(\mathbb{R}^2 \times \Omega')} + 1 \right) \left( \|u^\delta - u\|_{H^1(\mathbb{R}^2 \times \Omega')} + \|u\|_{L^2(\mathbb{R}^2 \times \Omega')} \right) \leq 2 \left( \|u\|_{H^1(\mathbb{R}^2 \times \Omega')} + 1 \right) \left( C_2 d^{1/4} + C_3 \sqrt{\delta} \right)
\leq C_6 (d^{1/4} + \sqrt{\delta}),
\]

where $C_6 = 2 \left( \|u\|_{H^1(\mathbb{R}^2 \times \Omega')} + 1 \right) (C_2 + C_3)$.

By combining (3.14) and (4.30), we can derive the estimate (3.18) from the triangle inequality $\|f^\delta - f^*\|_{L^2(\mathbb{R}^2 \times \Omega)} \leq \|f^\delta - f_0\|_{L^2(\mathbb{R}^2 \times \Omega)} + \|f_0 - f^*\|_{L^2(\mathbb{R}^2 \times \Omega)}$.

5. Numerical example.

5.1. Forward problem. We consider the following three-dimensional reaction-diffusion-advection equation with the given source function $f(x, y, z) = \cos (\pi x) \cos (\pi y) \cos (\pi z)$:

\[
\begin{align*}
0.01 \Delta u - \frac{\partial u}{\partial t} & = -u \left( \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} + \frac{\partial u}{\partial z} \right) + f(x, y, z), \\
u(x, y, -1, t) & = -4, \ u(x, y, 1, t) = 2, \ u(x, y, z, t) = u(x + 2, y, z, t) = u(x, y + 2, z, t), \\
u(x, y, z, 0) & = u_{\text{init}}(x, y, z, \mu), \\
x & \in [-1, 1], \ y \in [-1, 1], \ z \in [-1, 1], \ t \in [0, 0.5].
\end{align*}
\]

Using the asymptotic method, we reduce the original equation to two problems that determine the outer functions:

\[
\begin{align*}
\varphi^{(-)} \left( \frac{\partial \varphi^{(-)}}{\partial x} + \frac{\partial \varphi^{(-)}}{\partial y} + \frac{\partial \varphi^{(-)}}{\partial z} \right) & = \cos (\pi x) \cos (\pi y) \cos (\pi z), \\
\varphi^{(-)}(x, y, -1) & = -4, \ \varphi^{(-)}(x, y, z) = \varphi^{(-)}(x + 2, y, z) = \varphi^{(-)}(x, y + 2, z),
\end{align*}
\]

\[
\begin{align*}
\varphi^{(+)} \left( \frac{\partial \varphi^{(+)}}{\partial x} + \frac{\partial \varphi^{(+)}}{\partial y} + \frac{\partial \varphi^{(+)}}{\partial z} \right) & = \cos (\pi x) \cos (\pi y) \cos (\pi z), \\
\varphi^{(+)}(x, y, 1) & = 2, \ \varphi^{(+)}(x, y, z) = \varphi^{(+)}(x + 2, y, z) = \varphi^{(+)}(x, y + 2, z).
\end{align*}
\]
The problem of determining the leading term of the asymptotic description of the front $h_0(x, y, t)$ takes the form:

\[
\begin{cases}
    h_0 \left( 1 + h_0^2 + h_0^2 \right) = \frac{1}{2} \left( h_0x + h_0y - 1 \right) \left( \varphi^-(x, y, h_0) + \varphi^+(x, y, h_0) \right), \\
    h_0(x, y, 0) = h_0^* = 0, \quad h_0(x, y, 0) = h_0(x + 2, y, 0) = h_0(x, y + 2, 0).
\end{cases}
\]

From the numerical solution we see that the transition layer is located within the region $-1 \leq h_0(x, y, t) \leq 1$ for any $x \in [-1; 1], y \in [-1; 1]$ and $t \in [0, 0.5]$ (Fig. 1), thus, Assumption 2.3 is satisfied.

We find the numerical solution for (5.1) which we will use for the inverse problem; we take the initial function in the form

\[
(5.5) \quad u_{init}(x, y, z, \mu) = u^+ - u^- + \frac{u^+ + u^-}{2} \tanh \left( x + y + \frac{z - h_0(x, y, 0)}{0.1\mu} \right) + \frac{u^+ + u^-}{2} \tanh \left( x + y + \frac{z}{0.001} \right) - 1,
\]

with an inner transition layer in the vicinity of $h_0(x, y, 0) = 0$.

All the Assumptions formulated in this paper are satisfied and the considered equation (5.1) has the solution in the form of autowave with a transitional moving layer localized near $h_0(x, y, t)$, which in the zero approximation has the form:

\[
(5.6) \quad U_0 = \begin{cases}
    \varphi^-(x, y, z) + \frac{\varphi^+(x, y, h_0) - \varphi^-(x, y, h_0)}{\exp \left( \frac{(h_0-z)(\varphi^+(x, y, h_0)-\varphi^-(x, y, h_0))(1-h_0x-h_0y)}{2\mu} \right) + 1}, & z \in [-1; h_0], \\
    \varphi^+(x, y, z) + \frac{\varphi^-(x, y, h_0) - \varphi^+(x, y, h_0)}{\exp \left( \frac{(h_0-z)(\varphi^-(x, y, h_0)-\varphi^+(x, y, h_0))(1-h_0x-h_0y)}{2\mu} \right) + 1}, & z \in [h_0; 1].
\end{cases}
\]
We draw the asymptotic solution (5.6) at the moment \( t_0 = 0.4 \) on the Fig. 2(a). We also draw the numerical solution (by a finite volume method) for the problem (5.1) at the moment \( t_0 = 0.4 \) on the Fig 2(b), which we will use in the problem of identification the source function.

![Figure 2. Asymptotic solution ((a)) and numerical solution ((b)) of PDE (5.1) with \( t_0 = 0.4, \mu = 0.01 \).](image)

We find the the error of asymptotic solution:

\[
\frac{\|U_0(x, y, z, t_0) - u(x, y, z, t_0)\|_{L^2([-1,1] \times [-1,1] \times [-1,1])}}{\|u(x, y, z, t_0)\|_{L^2([-1,1] \times [-1,1] \times [-1,1])}} = 0.0735.
\]

5.2. Inverse problem. We consider the problem of identification of the source function \( f(x,y,z) \) of the problem (5.1) when only the measurements \( \{u^\delta_{i,j,k}\}^{pq,v} \) are provided, as a more complex scenario.

Since the functions \( \varphi^(-)(x, y, z) \) and \( \varphi^+(x, y, z) \) are solutions to the problems (5.2) and (5.3), the asymptotic analysis allows us to reduce the original inverse problem of determining the source function \( f(x,y,z) \) to a first-order equation of the asymptotic approximation of the solution of the direct problem.

We use the following parameters: \( a = 1, t_0 = 0.4, \delta = 5\%, p = 100, q = 100, v = 100, \nu^(-) = 58, \nu^+ = 73 \).

We take the data \( u(x_i, y_j, z_k, t_0) \) obtained from the numerical result for the forward problem (Fig. 2(b)) which belong to the mesh knots \( X_p = \{x_i, 0 \leq i \leq p : x_i = x_0 + d_1 i, d_1 = 2a/p\}, \)
\( Y_q = \{y_j, 0 \leq j \leq q : y_j = y_0 + d_2 j, d_2 = 2a/q\}, \)
\( Z_v = \{z_k, 0 \leq k \leq v : z_k = -a + d_3 k, d_3 = 2a/v\}. \) The points belonging to the transitional layer \( (h_0(x,y,t_0) - \Delta h/2, h_0(x,y,t_0) + \Delta h/2) \) was removed, so we use only the points with indices \( i = 0, \ldots, p, j = 0, \ldots, q \) and \( k = 0, \ldots, \nu^(-), \nu^+, \ldots, v \). We generate the artificial noisy data by adding the uniform noise with \( \delta = 5\% \) to the values \( u(x_i, y_j, z_k, t_0) \) (Fig. 3(a)):

\[
u^\delta_{i,j,k} := [1 + \delta(2 \text{rand} - 1)]u(x_i, y_j, y_k, t_0),
\]
where “rand” returns a pseudo-random value drawn from a uniform distribution on $[0, 1]$.

Following Algorithm 1, we smooth the noisy data on the both regions by equations (3.16) and (3.17) and obtain the smooth function $u^\varepsilon(x, y, z, t_0)$ (Fig. 3(b)).

After we calculate the regularized approximate source function $f^\delta$ by formula (3.15) and compare it with the exact source function $f^\star(x, y, z) = \cos(\pi x) \cos(\pi y) \cos(\pi z)$ (Fig. 4).

The relative error of reconstruction the source function for the noise $\delta = 5\%$:

$$\frac{\|f^\delta - f^\star\|_{L^2([-1,1] \times [-1,1] \times [-1,1])}}{\|f^\star\|_{L^2([-1,1] \times [-1,1] \times [-1,1])}} = 0.3674.$$

6. Conclusion. In this paper, by using an asymptotic expansion method, we developed an efficient approach for the approximate solution of both forward and inverse problems, associated with a three-dimensional nonlinear PDE of the reaction-diffusion-advection type with an internal transition layer. The merit of our approach is twofold. First, incorporating with the asymptotic method of inequalities, the existence and uniqueness of a classical solution of PDE can be easily proven. Second, the procedure of asymptotic expansion can be used as a procedure of model reduction for some inverse problems: during the construction of asymptotic solution, a link equation between measurement and unknown quantity can be obtained.

It should be noted that our approach can be easily employed to many other similar problems of mathematical physics. For instance, the current model (1.1) can be views as a special case of the following general model:

$$\mu \Delta u - \frac{\partial u}{\partial t} = (A(u, x, y, z), \nabla) u + F(u, x, y, z),$$

where $A(u, x, y, z) = \{A_1(u, x, y, z), A_2(u, x, y, z), A_3(u, x, y, z)\}$. If the functions $A_1, A_2, A_3$ and $F$ are chosen so that it is possible to obtain explicit solutions for the inner and outer functions, all results in this paper can be derived similarly.
